The NOVA School of Science and Technology and the NOVA University Lisbon have the right, perpetual and without geographical boundaries, to file and publish this dissertation through printed copies reproduced on paper or on digital form, or by any other means known or that may be invented, and to disseminate through scientific repositories and admit its copying and distribution for non-commercial, educational or research purposes, as long as credit is given to the author and editor.

ACKNOWLEDGEMENTS

First and foremost, I would like to express my sincere gratitude to my advisor, Armando Rodrigues, and co-advisors, Inês Coutinho and Nuno Correia. Their assistance and support were priceless throughout this dissertation.

I am also extremely grateful to the Department of Computer Science for providing all the necessary resources and facilities to carry out this work. My thanks also go to the research center VICARTE for the support, materials, and space that made it possible to conduct the user evaluation.

A special thanks to Inês Vaz Pinto, responsible for the Roman Ruins of Troia, for her openness and availability in welcoming us to visit the space, as well as for the necessary materials she kindly provided, which were fundamental to achieving the desired results. I would also like to acknowledge Sofia Pires for her contribution in providing the 3D models of the artefacts, and to Professor João Lourenço for making the report template openly available.

Finally, a big thank you to my family and friends for their constant encouragement and support during this dissertation and my entire academic journey.

”

“A dream doesn’t become reality through magic; it takes sweat, determination and hard work.”

— Colin Powell

ABSTRACT

Nowadays, the significant historical and cultural heritage of the Roman Ruins of Troia remains largely unknown to the public. This dissertation focuses on unique luxury glass artefacts found in a recently discovered Roman tomb in Troia, Setúbal.

The need to raise awareness of this valuable discovery led to the collaboration between the Computer Science and Conservation and Restoration departments at NOVA FCT and archaeologists from the Roman Ruins of Troia. The project involved the development of a virtual reality environment to disseminate this study, preserve its cultural value, share its findings, and offer great potential for future progress.

This work covers the integration of collected data, including excavation records, interventions, and artefact data from the site, and the preliminary development of a virtual reality application. The collected data is stored in a database that serves as a central repository. The virtual environment presents an experience focusing on virtually immersing users in a visit to an existing tomb within a funerary enclosure featuring two objects and an interactive base map of the western archaeological site of Troia. The funerary enclosure and objects were integrated into the environment as 3D models. Additionally, the users can interact with a virtual panel, view details about objects, toggle the site plan, and view a funerary profile. These elements allow users to explore a map featuring a funerary enclosure and engage with rare luxury artefacts from the Roman Empire.

In a final stage, the resulting experience was tested with 28 participants from diverse backgrounds. The results were evaluated through a questionnaire assessing task usability, sense of presence, and overall user experience. The evaluation indicated a generally positive outcome, with a few improvements subsequently implemented based on user feedback.

Keywords: Cultural Heritage, Troia, Virtual Reality, Rare Artefacts, Roman Empire

RESUMO

Nos dias de hoje, um tesouro histórico-cultural situado em Troia permanece maioritariamente desconhecido. Esta dissertação foca-se em artefactos de vidros luxuosos e únicos do período romano, encontrados recentemente numa tumba descoberta em Troia, Setúbal.

A necessidade de dar a conhecer esta valiosa descoberta levou à colaboração entre os Departamentos de Informática e Conservação e Restauro da NOVA FCT e arqueólogos das Ruínas Romanas de Troia. O projeto envolveu o desenvolvimento de um ambiente virtual para disseminar este estudo, preservar o seu valor cultural, partilhar os seus resultados, e potencializar o seu futuro progresso.

Este trabalho abrange a integração dos dados recolhidos, incluindo regtos de escavações, intervenções e dados de artefactos do sítio arqueológico, e o desenvolvimento preliminar de uma aplicação de realidade virtual. Os dados recolhidos são armazenados numa base de dados que é um repositório central. O ambiente virtual proporciona uma imersão virtual numa visita a um túmulo inserido num recinto funerário, com dois objetos, e inclui um mapa base interativo da área ocidental do sítio arqueológico de Troia. O recinto funerário e os objetos foram integrados no ambiente virtual sob a forma de modelos 3D. Além disso, os utilizadores podem interagir com um painel virtual, visualizar detalhes sobre os objetos, alternar a planta do local e visualizar um perfil do funerário. Estes elementos permitem aos utilizadores explorar o recinto funerário e interagir com alguns dos artefactos mais raros do Império Romano.

Numa etapa final, a experiência foi testada com 28 participantes de diferentes contextos. Os resultados foram avaliados através de um questionário contendo a usabilidade da tarefa, o sentimento de presença e a experiência global do utilizador. A avaliação indicou um resultado global positivo, com algumas melhorias posteriormente implementadas com base no feedback dos utilizadores.

INTRODUCTION

This chapter includes a concise overview of the topic of this dissertation. Section 1.1 introduces the motivation behind this thesis, while Section 1.2 describes its context. Following, Section 1.3 presents the problem and the main objectives accomplished with this study. The contributions of this dissertation are summarized in Section 1.4. Finally, in Section 1.5, the report organization is outlined.

1.1 Motivation

This project studies the exploration of luxury glass from ancient Rome. The central motivation of this dissertation is the research of remains and artefacts, not only to preserve the Cultural Heritage (CH) but also to convey ancestral heritage knowledge to everyone, including future generations. The growing integration of digital tools with arts and material culture enhances online facilities for users and democratizes its access. Additionally, it cultivates a deeper understanding of ancient cultures and traditions, allowing more people to engage with CH in meaningful ways. Moreover, by integrating technology with these archaeological discoveries, the goal is to raise the value of this archaeological site and make it accessible in an immersive and engaging Virtual Reality (VR) experience.

1.2 Context

This thesis was developed under the umbrella of an interdisciplinary collaboration among three institutions. The NOVA LINCS¹, Glass and Ceramic for the Arts (VICARTE)², and archaeologists from the Roman Ruins of Troia. VICARTE is a research unit focused on glass and ceramics, established as a partnership between NOVA University Lisbon (NOVA) and the Faculty of Fine Arts, University of Lisbon, with contributions from the Faculty of Fine Arts, University of Oporto, School of Arts and Design, Polytechnic Institute of Leiria, and Cultural Institutions. The research carried out at VICARTE is structured on

¹<https://nova-linacs.di.fct.unl.pt/>

²<https://vicarte.org/about-us/>

two interconnecting pillars: the study of Glass and Ceramics in Contemporaneity and in CH. Historically, the Roman Ruins of Troia are recognized as the largest fish-salting production complex from the Roman period, active from the beginning of the 1st century until the 6th century. The site of Troia is located on the southwestern coast of Portugal, on a sand embankment between the estuary of the Sado River and the Atlantic Ocean [31].

The archaeological site stretches for about two kilometers along the Sado River estuary, and contains thirty fish-salting workshops [19]. With its significant historical and cultural value, the site of Troia has strongly influenced the economic and cultural development of the surrounding region up to the present. In 2005, a protocol was established that enabled the hiring of an archaeological team responsible for the preservation, maintenance, and enhancement of the Troia archaeological remains [32]. Two years later, a project was initiated to make the Roman ruins accessible to visitors, including the creation of pathways with interpretative panels. The Roman Ruins of Troia were opened to the public in 2011. Currently, artefact collections from Troia are exhibited in various institutions, including the National Museum of Archaeology (NMA)³, the Museum of Archaeology and Ethnography of the District of Setúbal⁴, and the City Council of Grândola⁵. The specific glass artefacts under study are housed at the NMA.

1.3 Problem Description and Objectives

This thesis concentrates on the study of glass relics discovered in the tomb of a wealthy woman who lived in the Troia Peninsula. The data collected from the studies and excavations of this site include data from the artefacts, excavation, and intervention process, such as images of the discovered glasses both before and after conservation. The preservation intervention work was carried out at VICARTE, that provided access to the images mentioned.

This project comprises two digital tools developed in parallel, complemented by a third component responsible for managing communication between them.

Primarily, a data repository was designed to compile and organize findings from a Troia funerary enclosure, focusing specifically on glass objects found inside. A database was structured to store this data. This database stores essential objects' information, such as object ID, dimensions, location details, object utility, shape, conservation status, and provenance. It serves as a data source for the Virtual Environment (VE).

The second tool, and the main focus of this dissertation, is a VR experience focusing on an immersive visit to an existing physical artefact, to enable visitors to handle precious fragile antiquities, added to the environment as 3D models. Two of these object models are already completed and were supplied by the researchers involved in the project. Furthermore, the application provides users with the option to experience a simulation of

³<https://www.museunacionalarqueologia.gov.pt/>

⁴<https://maeds.amrs.pt/>

⁵<https://www.cm-grandola.pt/>

the original appearance of the glass artefacts. In this environment, an interactive map of the Troia occidental site was integrated, featuring tooltips, Points of Interest (POIs), and the 3D model of the tomb within the funerary enclosure model positioned above the map, and developed from a photogrammetry capture. The map is the base ground plane on which users can walk and explore, with an additional functionality that enables toggling to another layer of the site. The user interaction with the environment is supported through the use of the VR headset display.

In addition, a backend implementation serves as the backbone of the two interactive tools described, supplying the VE with informative data retrieved from the repository.

1.4 Main Contributions

The main contributions achieved in this dissertation are:

- **Data Repository** - A comprehensive database containing all available data, accessible to users through interactions with the VR environment.
- **VR Immersive Experience** - Enables users to view and explore the funerary enclosure model with the map as ground plane, and interact with and manipulate virtual 3D objects within. An innovative feature is the opportunity for users to virtually interact with glass-made historical relics, offering a sense of traveling back in time. Users can also navigate through a user-friendly map that enhances the feeling of presence within this authentic CH space. Additionally, the system delivers an engaging and interactive experience that enriches their understanding and interest in Roman heritage, making learning both enjoyable and meaningful.
- **Research Paper Publication and Presentation** - During the dissertation, a short paper based on the developed work was written, submitted, and accepted for publication at the *SUMAC Workshop on Analysis, Understanding, and Promotion of Heritage Contents*⁶, part of the ACM Multimedia 2025 Conference⁷, to be held in Dublin, Ireland. The corresponding workshop and poster presentation will take place on 27 October 2025.

1.5 Document Structure

This document is structured into seven chapters:

1. **Introduction:** The first chapter introduces the theme of the dissertation and explains its main focus.
2. **Fundamental Concepts:** This chapter provides background on the key areas of this thesis and explains significant concepts that were explored throughout the work.

⁶<https://sumac-workshops.github.io/2025/>

⁷<https://acmmm2025.org/>

3. **Related Work:** This segment consists of the research of similar projects and analysis of digital tools from relevant studies that can complement this dissertation.
4. **System Design:** This chapter presents the requirements and design decisions that guided the system's implementation.
5. **Implementation Details:** This chapter describes the implementation process. Code listings are included to illustrate technical details, while figures demonstrate the system's functionalities.
6. **User Evaluation:** The following chapter describes the evaluation methodology, including the questionnaires and procedures used to assess user experience in the VE developed. The chapter also presents and analyses the collected results, supported by graphics.
7. **Conclusions:** The final chapter summarizes the achieved goals, encountered challenges, and possible future improvements.

FUNDAMENTAL CONCEPTS

This chapter introduces key concepts related to this thesis. Section 2.1 provides background of relevant digital aspects in Cultural Heritage (CH). Subsequently, Section 2.2 explores Virtual Environments (VEs), focusing on user interaction and visualization. Section 2.3 presents diverse 3D extracting methodologies. Section 2.4 examines the role of Geographic Information Systems (GISs) in applications involving map integration, particularly in the context of archaeological sites. The last two sections address important standards, and documentation principles (Section 2.5) to consider when developing heritage applications, as well as a significant European Union initiative (Section 2.6).

2.1 Digital Heritage Foundations

This section covers the fundamental concepts for integrating digital tools to visualize and preserve artefacts during archaeological studies.

2.1.1 Digital Cultural Heritage (DCH)

CH includes monuments, sites, landscapes, skills, practices, knowledge, and expressions of human creativity [11]. Collections preserved and managed by public and private bodies - such as museums, libraries and archives - and film heritage are also part of CH. As a fundamental legacy, CH engages people and contributes to the enrichment of society. It can take tangible forms, such as monuments or artworks; intangible forms, such as songs and traditions; or digital forms, whether born-digital or digitised.

In this thesis, tangible objects were digitally reproduced and represented as 3D models.

Digital technologies offer new possibilities to preserve cultural content and to make CH more accessible to all audiences [12]. Museums and cultural organisations that embrace technology are able to offer innovative visitor experiences, as well as let the public access exhibitions remotely and view material that is not on display. The European Union (EU) funds an extensive list of projects combining technology and art. Europeana¹ is a European digital platform that provides free access to digitised cultural heritage collections from

¹<https://www.europeana.eu/>

CHAPTER 2. FUNDAMENTAL CONCEPTS

museums, libraries, and archives, supporting research, education, and facilitating public engagement.

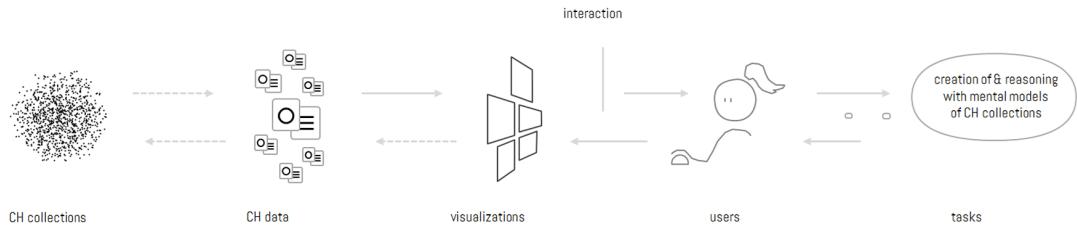

Figure 2.1: Schematic lineup of a visualization system in the CH data domain [48].

The visualization of CH collections (process illustrated in Figure 2.1) can involve two classes of data: the data constituting the digital cultural object, and the accompanying metadata [48]. The metadata can describe a broad diversity of information associated with CH objects, as represented in Figure 2.2. Furthermore, digital CH collections are employed by a wide range of users, including researchers, archaeologists, humanities students, and members of the general public.

Therefore, to systematically classify different types of metadata, it is essential to adopt a unified metadata model. Among several standardization initiatives, the Europeana Data Model (EDM)² is one of the most mature efforts. The EDM reuses several existing Semantic Web vocabularies, such as the metadata set of the Dublin Core Metadata Initiative (DCMI)³, and the CIDOC Conceptual Reference Model (CIDOC-CRM)⁴ from the International Committee for Documentation (CIDOC) of the International Council of Museums⁵.

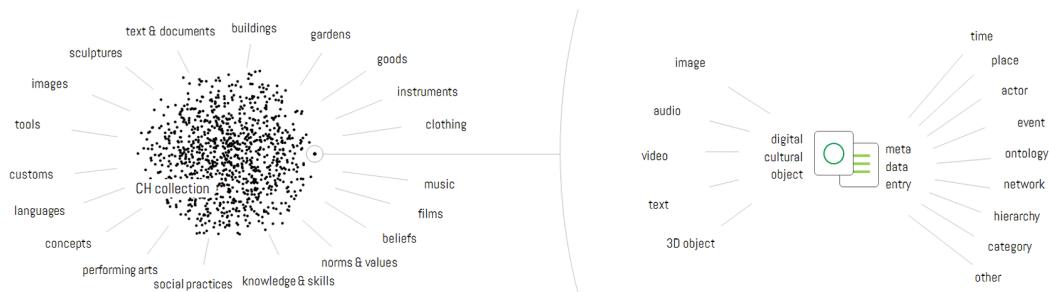

Figure 2.2: Types of cultural objects and related metadata entries [48].

2.1.2 Virtual Heritage Environment

According to Hale and Stanney (2014), "VE is a model of reality with which a human can interact, getting information from the model by ordinary human senses such as sight,

²<https://pro.europeana.eu/page/edm-documentation>

³<https://www.dublincore.org/>

⁴<https://cidoc-crm.org/>

⁵<https://icom.museum/>

sound, and touch" [18]. It also enables control of the model through typical citizen actions, such as the movement and positioning of body parts and voice. Although the terms VE and VR are frequently used interchangeably, some authors reserve the VE for an artificial environment which the user interacts with.

Virtual heritage involves the use of interactive digital technologies to record, preserve, and recreate culturally relevant artefacts and sites [42]. It allows digitally preserved content to be shared globally, providing an educational experience that enables users to explore CH through virtual manipulations of time and space. Given the need for interactivity with virtual objects, we naturally will use a VE to represent heritage artefacts in 3D in this project, enabling users to explore and interact with CH in an immersive and educational way.

Since the 1990s, VR was continuously used to recreate historical sites in a virtual immersive environment [18]. This technology provides a way to protect fragile sites while simultaneously educating visitors on how to explore, comprehend, and appreciate significant heritage sites.

2.1.3 Digital Twins in Cultural Heritage

Generically, the Digital Twin (DT) can be understood as a probabilistic, multiscale, multiphysics integrated simulation of a system that uses the best physical models, sensors, and history to mirror the life cycle of its corresponding twin [9]. The DT consists of three components: physical product in a real monitored space, data and information connections, and the corresponding virtual product in virtual space [16].

A potential application of the DT technology for heritage is its accurate representation in the form of an intelligent and semantically enriched 3D model Heritage Building Information Modelling (HBIM). First defined in 2009, HBIM is "a novel solution whereby interactive parametric objects representing architectural elements are constructed from historic data, these elements are accurately mapped onto a point cloud or image-based survey" [28]. This is a powerful tool capable of managing information collected and modeled, improving its availability and accessibility. Digital scanning technologies, including photogrammetry and laser scanning, are employed to capture detailed 3D representations. In the context of historic buildings, they facilitate the assessment of current conditions and expedite the generation of corresponding 3D digital models.

Implementing a DT for the management and preservation of CH assets requires adopting a collaborative integrated approach and fostering strong interplay among heritage recorders, conservation experts, and information and communications technology specialists. Additionally, the adoption of open standards to document risk management and potential interventions is essential, ensuring interoperability across diverse information systems and enhancing understanding of the interrelationships within the DT. Developing effective preventive conservation strategies require a in-depth understanding of the heritage site and its context, and value. Proper management of the information collected

during documentation needs thoughtful selection of an appropriate Heritage Information System (HIS). GIS is often used to represent complex cultural heritage data through 3D visualization. In this context, researchers have increasingly regarded HBIM as a valuable alternative. [21].

2.2 Interaction and Visualization Technologies

This section analyses virtual interactions from a technical perspective, and on the technologies used to create them. The first subsection (Section 2.2.1) lists the various user task interactors. Section 2.2.2 explores alternative methods of interacting with displays. Finally, the last sections discuss how to create a virtual simulation environment and enhance immersive interactions (Section 2.2.3 and Section 2.2.4).

2.2.1 Virtual Environment Interactors

A 3D interactor is generally a geometric object with a defined behavior when certain events occur and certain properties of the environment and the objects in it change [18].

As is true of 2D graphical applications, a 3D environment may contain geometric objects that belong to a class that interact with the user and other objects in a well-defined way. In 2D interfaces, these objects are called widgets, components, or interactors and include buttons, menus, scrollbars, and pointers. Each class of object encapsulates an interactive behavior, parameterized to allow for multiple uses.

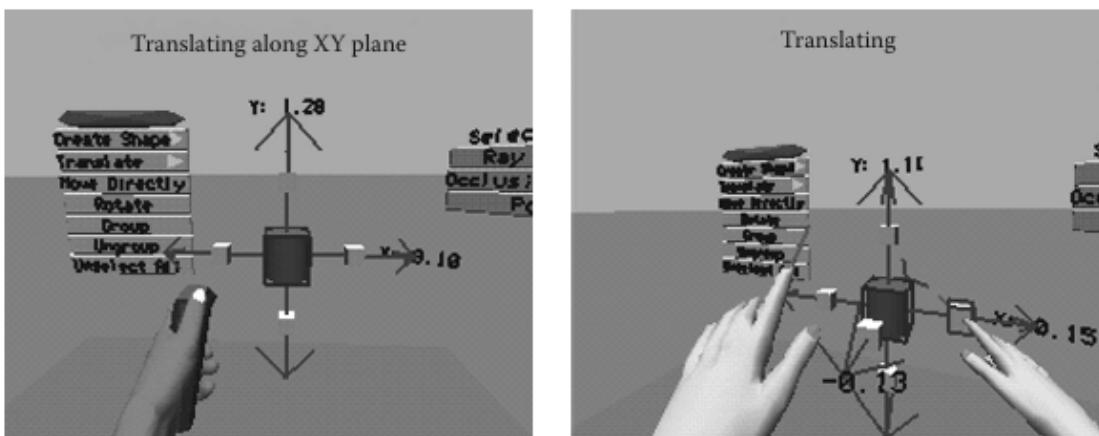

Figure 2.3: VR interface where a user is manipulating a 3D object [18].

Figure 2.3 above contains a set of Simple Virtual Interactor Framework and Toolkit (SVIFT) interactors, including buttons, menus, and tabs that can be grabbed and moved (or bestow the grab and move ability to another object), constraint maintainers (e.g., keeping the manipulated object on a particular plane), and selectors. The image on the left is using a ray selector interactor, while the figure on the right is using a poking selector.

2.2.2 Hardware Interaction

This section presents the possible user interactions with VEs, achieved through user tasks using input controllers and output devices connected to physical displays.

2.2.2.1 Input Devices

Common VE input devices include Six Degrees of Freedom (6-DOF) trackers⁶ as exemplified in Figure 2.4, gloves capable of recognizing continuous postures or discrete events, pen-like, simple button devices, as well as specialized tools such as the Spaceball or joysticks with force-feedback.

In the next paragraphs, I will describe four common available VE task categories.

Selection is the process of specifying an object or set of objects for a particular action. Most selection techniques can be categorized based on how an object is indicated, whether by touching it with a virtual hand, pointing at it, occluding it, encapsulating it within a volume, or selecting it indirectly.

Manipulation can be understood as the modification of an object's attributes, such as its identifier, name, position, scale, or texture. These tasks are particularly significant in fields like design, prototyping, simulation, and entertainment, where environments frequently need to be adjusted by the user. The design space for manipulation techniques is quite large. To provide a simple overview of the techniques already developed in the design space, three categories are presented in the following—virtual hand, proxy, and indirect.

Travel, also called viewpoint motion control, is the most ubiquitous and common VE interaction task. Consists simply of the user's movement inside the environment. Travel and wayfinding make up the task of navigation. Most travel techniques can be categorized as physical locomotion, steering, automated, or manual manipulation. Many of the other interactions found in VE applications fall under the heading of system control.

System control involves operations such as executing commands, changing modes, or modifying the system state. The categories of system control techniques include virtual menus, voice commands, tools, and gesture-based interactions.

Figure 2.4: HTC Vive controllers(center) and Oculus Touch controllers(at the ends) [40].

⁶<https://www.ar.rocks/glossary/6dof-tracking>

2.2.2.2 Output Devices

The three common VE display devices are Head-Mounted Displays (HMDs), as illustrated in Figure 2.7, Spatially Immersive Displays (SIDs) (fully or semisurrounding displays, such as the Cave Automatic Virtual Environment (CAVE)⁷) (Figure 2.5), and single-screen stereo displays, such as the Responsive Workbench⁸. The user interaction with these last displays is very different, as shown in Figure 2.6. HMDs and fully surrounding SIDs provide the ability to view the entire VE by physically turning. Since semisurrounding SIDs rely on virtual rotations, applications for these displays should be designed to minimize the occurrence of such undesirable movements. HMDs that have a narrow Field of View (FOV) require extensive head rotation in order for the user to see the entire environment.

Figure 2.5: Stereoscopic glasses augmented with a constellation of reflective balls [38].

Figure 2.6: Dual-screen fishtank stereo-capable display [38].

⁷<https://steantycip.com/vr-cave/>

⁸<https://graphics.stanford.edu/projects/RWB/>

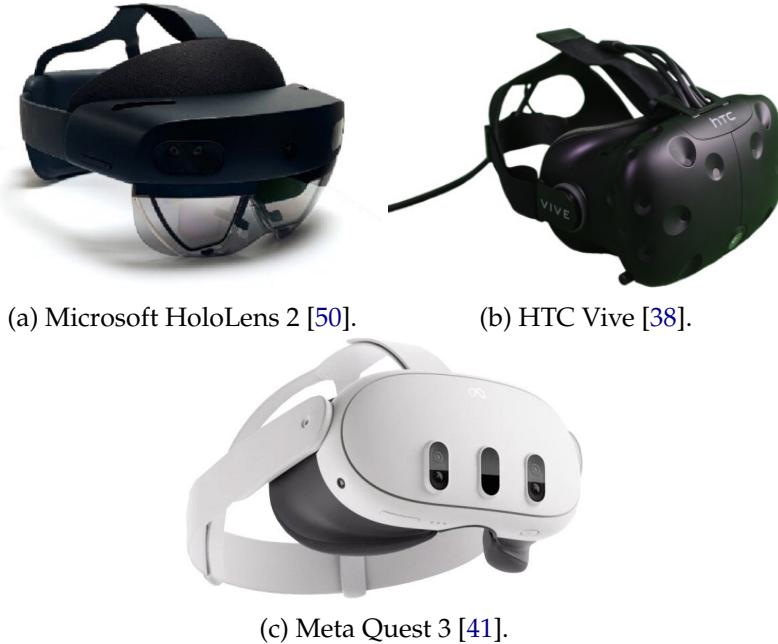

Figure 2.7: Examples of the most recent and advanced HMDs.

2.2.3 Virtual Reality

VR is a sophisticated technology that enables users to engage with a computer-generated environment in an interactive and immersive way. Instead of relying on traditional screens or input commands, VR provides users a multisensorial experience. Including move freely, view and navigate in digital spaces from multiple perspectives, and manipulate objects as if they were physically present. This is possible through VR devices equipped with motion tracking and controllers, enhancing the sense of presence and realism.

The industry of VR combines expertise from diverse disciplines, including engineering, cybernetics, database management, real-time computing, simulation, computer graphics, ergonomics, stereoscopic imaging, anatomy, and even artificial intelligence. Despite its continuously advancements, VR still faces significant challenges, such as improving software performance, hardware capabilities, user interaction design, and high-speed network integration.

2.2.4 Augmented Reality vs Virtual Reality

While VR technology, or VE as called by Milgram, completely immerses users in a synthetic world without seeing the real world, Augmented Reality (AR) technology augments the sense of reality by superimposing virtual objects and cues upon the real world in real time.

The Virtuality Continuum is defined by Paul Milgram and Fumio Kishino [27] as a continuum that spans between the real environment and the virtual environment comprise AR and Augmented Virtuality (AV) in between, where AR is closer to the real world, and AV is closer to a pure VE, as seen in the Figure 2.8.

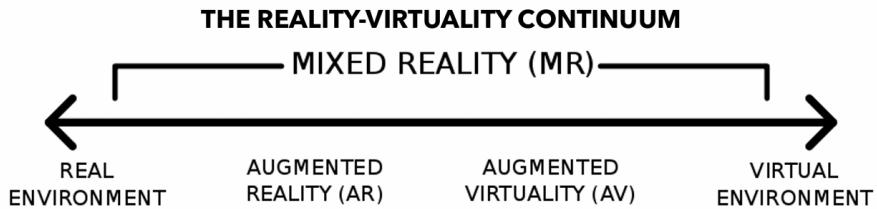

Figure 2.8: Milgram and Kishino’s Virtuality Continuum [27].

2.3 3D Data Acquisition and Visualization

This section describes various techniques used for data acquisition, such as digital cameras and scanners and visualization through 3D models created with advanced software and further enhanced. The final subsection explores approaches for artefact reconstruction and the overall process.

2.3.1 Photogrammetry

Photogrammetry is a measurement technique that is used to extract the geometry, displacement, and deformation of a structure using photographs or digital images [4].

Concerning the object(s) of interest and the camera position(s), we distinguish between terrestrial and aerial photogrammetry [24]. Aerial photogrammetry involves capturing images from an aircraft in overhead views, which are then used to generate topographic maps. By contrast, terrestrial photogrammetry captures images from positions on or near the Earth’s surface, enabling the extraction of precise details about objects. When the object size and the camera-to-object distance are both less than 100 meters, terrestrial photogrammetry is further defined as close-range photogrammetry. A fundamental technique in photogrammetry for creating accurate 3D models is Stereoscopic Viewing. By capturing two or more images photos of the same object but taken from different positions, it is possible to calculate the 3D coordinates of any point which is represented in both photos [24].

Multi-image photogrammetry is an advanced technique that combines large groups of images to create detailed 3D models [26]. The process begins with image acquisition, followed by importing the images into specialized software that automatically detects and matches correlated features. This step can be highly time-consuming and demand computer power for large datasets. Once matching points are identified, the software calculates their spatial relationships, producing a sparse 3D point cloud that outlines the subject’s shape, as shown in Figure 2.9. Finally, the software refines this sparse model by reanalysing the images to generate a much denser point cloud, similar to those produced by laser scanners.

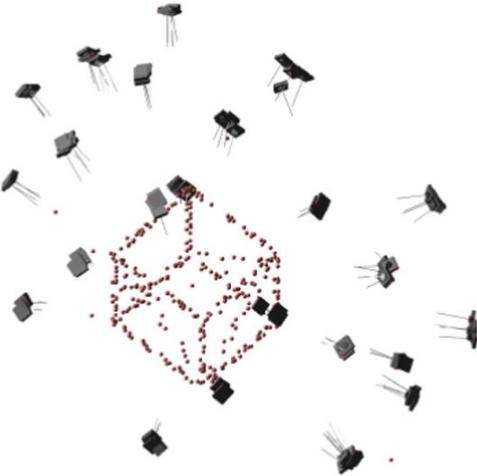

Figure 2.9: 131 images of a 3D object in all-around configuration [25].

The most valuable application of multi-image photogrammetry may lie in its ability to facilitate community engagement in archaeological documentation. This approach enables the efficient creation of interactive 3D models, allowing the public to engage with heritage sites in a more immersive way than traditional static representations such as site plans and sectional drawings.

2.3.2 Light Detection and Ranging (LiDAR)

LiDAR sensors enable precise 3D sensing of objects and are widely used in metrology, environment monitoring, archaeology, and robotics [23]. This technology allows for accurate determination of an object's distance and velocity. Similar to photogrammetry, LiDAR scanning is classified into two main types: terrestrial and airborne. The three most significant approaches in LiDAR technology are mechanical, nanophotonics-based, and solid-state. In traditional LiDAR sensors, as shown in Figure 2.10, a mechanical rotator is used for optical beam scanning, which introduces limitations on their reliability, size, and cost.

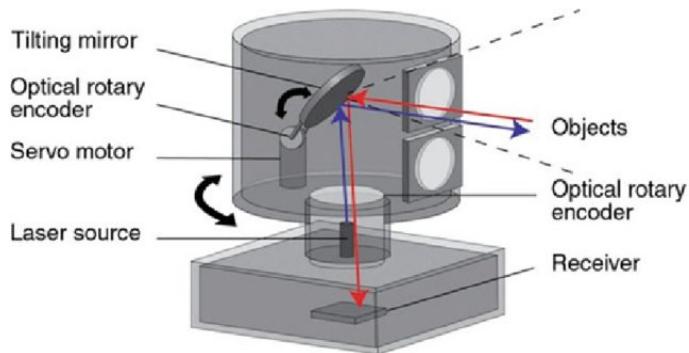

Figure 2.10: Mechanical Spinning LiDAR [20].

Solid-state LiDAR presents an alternative to traditional LiDAR by eliminating the need

for a bulky mechanical rotator. Moreover, advancements in optical technology have led to the development of nanophotonics-based devices with high potential and superior advantages for LiDAR sensors. Different scanning techniques produce diverse types of scan outputs. For instance, flash-based LiDAR from solid-state approach captures a full-frame 3D image in a single snapshot, as shown in Figure 2.11, while sequential illumination-based LiDAR scans objects by sequentially illuminating small regions, producing the whole frame, as depicted in Figure 2.12.

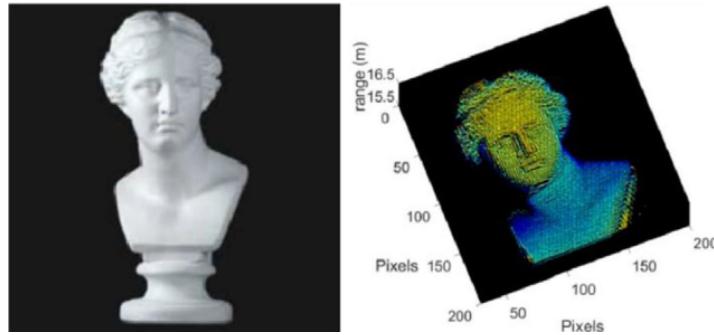

Figure 2.11: Flash-based LiDAR sensor. Left: 2D image of sensing target, Right: Captured 3D image [23].

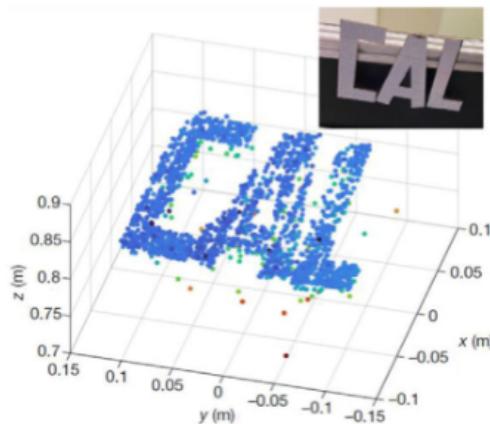

Figure 2.12: A LiDAR sensor based on sequential illumination [23].

2.3.3 Artifacts Reconstruction

Systems capable of automatically reconstructing objects from their fragments can greatly aid in the study of many civilizations [47]. Automated reconstruction systems working from large databases of digitized fragments could uncover numerous partial or complete reconstructions of artefacts that may have been excavated during different years of the same excavation, or possibly from different sites altogether. In this way, reconstruction systems not only save researchers time but, given a sufficient database of fragments,

also have the capacity to reconstruct artefacts that would have otherwise remained as an incoherent pile of disjoint fragments .

Precise shape measurement can be achieved using advanced laser scanners or other commercially available shape measuring devices based on stereo vision or structured light [17]. A detailed triangulated 3D model of a corrupted shape is the prerequisite for its subsequent reconstruction. Missing or scarred parts of a shape can be reconstructed from similar parts either from the same object or by using a similar object as reference. If an object has symmetrical features, the missing or damaged part can be restored by copying the undamaged side. To fix scar parts or gaps, a mathematical technique called surface spline patches is used to smoothly fill in and blend the missing areas.

2.4 Geospatial Data and Systems

A Geographic Information System (GIS) is a computer-based system designed to manage, analyse, and represent geographical information. This system typically integrates geographically referenced data with an associated database repository, allowing users to visualize and explore data and comprehend spatial patterns integrated based on location. [39]

In the context of GIS and geospatial data, two of the most prominent community initiatives are the Open Geospatial Consortium (OGC)⁹ and the Open Source Geospatial Foundation (OSGeo)¹⁰. The OGC is an international voluntary consensus standards organization, constituting more than 450 strong united organizations (such as Esri¹¹, Nasa¹²). The consortium publishes open standards that ensure interoperability between diverse GIS¹³. The OSGeo is an organization that promotes global adoption of open geospatial technology through an open philosophy and community driven development.

The first subsection provides an overview of geospatial data and its usage, while the following section explores its applications in archaeology.

2.4.1 Geospatial Data

GIS applications may include diverse spatial data types, such as cartographic data, photographic data, digital data, or data in spreadsheets. Once all the desired data have been entered into a GIS system, they can be combined to produce a wide variety of maps, that highlight different spatial relationships depending on the selected data layers. One of the most common uses of GIS technology involves comparing natural features with human activity, as illustrated in Figure 2.13.

⁹<https://www.ogc.org/>

¹⁰<https://www.osgeo.org/>

¹¹<https://www.esri.com/>

¹²<https://www.nasa.gov/>

¹³<https://ogcapi.ogc.org/>

Maps help visualize relationships between spaces and objects in proximity, aiding spatial analysis to identify patterns and make informed decisions based on data. A classic example of this geographic method is Jon Snow's study during the cholera epidemic in London in 1854 [20]. Jon Snow plotted the locations of cholera cases against the location of water pumps and noticed that the epidemic was concentrated in a certain neighborhood. Through the causal linkages, it was proven that when the contaminated pump was closed, the epidemic quickly came to a halt. A map of just the water pumps or incidences of cholera would have been of little value, but combining both revealed the contaminated source.

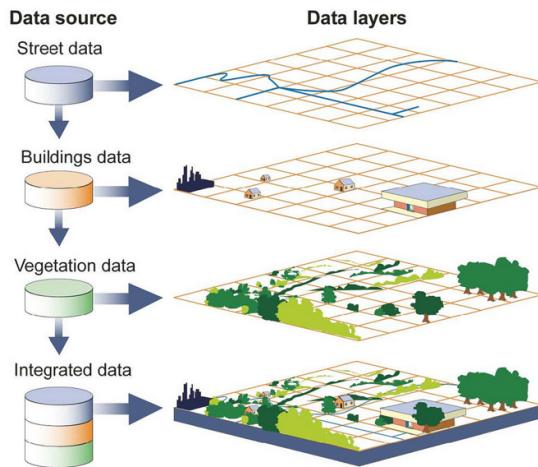

Figure 2.13: Visual Representation of Data Layers Integration in a GIS [30].

2.4.2 GIS Applications in Archaeology

The application of GIS in archaeology has brought about a transformative shift, equipping archaeologists with powerful tools to collect, analyse, and visualize geospatial data from archaeological sites [51]. Since 2000, GIS has been employed for complex spatial analyses, including landscape analysis and site distribution patterns. The development of the 3D GIS technology allowed the reconstruction of ancient CH sites in VEs, thereby providing engaging experiences while visualizing heritage monuments at archaeological sites.

A key technology that complements GIS in archaeology is LiDAR. The employment of LiDAR has been successful as an archaeological surveying tool for locating and identifying sites, sometimes in very remote and difficult to access locations [36]. For example, the recent, and highly publicized, discovery of what is believed to be the Mayan site of Ciudad Blanca in Honduras [43].

GIS can be employed for the management of CH resources, providing efficient handling of CH data. A key application of GIS is the documentation of CH sites, including, for example, georeferenced data from Points of Interest (POIs) within archaeological sites. This approach enhances the preservation of CH findings while allowing the associated data to be accessed and updated as needed.

With advancements in 3D graphics, high-resolution rendering, artificial intelligence, and 3D printing, those methodologies have progressively found widespread application in the preventive protection and restoration of cultural artefacts. In archaeology, GIS is essential for managing spatial data, often integrating spatial databases, such as PostgreSQL¹⁴/PostGIS¹⁵ or Oracle Spatial¹⁶ for efficient data storage and querying. Moreover, software such as ArcGIS Pro¹⁷ or QGIS¹⁸ is used to visualize, analyse, and interpret this data. These GISs process archaeological data following specific data standards and protocols.

2.5 Heritage Metadata Standards and Documentation

Standards are critical for systematic and robust development of any emerging technology [18]. Specification standards provide for practical descriptions of product characteristics and limitations, critical to an end user. Interface standards allow for interchangeability of components developed by different manufacturers, thus enabling specialization and robust competition in the marketplace. Safety standards ensure the health and safety of product users. Finally, terminology standards ensure that technical terminology is used in a consistent and rigorous manner, thus preventing confusion and ambiguity in scientific and technical reports and specifications.

In the subsections below, the first presents a commonly used model with aggregated standards, followed by a significant European organization in CH preservation.

2.5.1 CIDOC Conceptual Reference Model

The CIDOC-CRM¹⁹ is a theoretical and practical tool for integrating CH information [3]. It provides formal definitions and a structured framework to describe concepts and relationships that support the organization and connection of information regarding CH objects and their contexts (Figure 2.14). Since 2006, CIDOC-CRM has been recognized as an official ISO standard (ISO 21127:2023). The most recent version establishes CIDOC-CRM as a compatible interface for OGC standards, enhancing its application in GIS and facilitating geospatial and spatiotemporal reasoning.

From database to CIDOC-CRM

The necessary information is extracted from different archaeological and museum collection data models (with various structured, as well as non-structured data, i.e. text description) to a common standard based on CIDOC-CRM compliant structure. Although the CIDOC-CRM model provides a common, standardized framework for representing

¹⁹<https://cidoc-crm.org/>

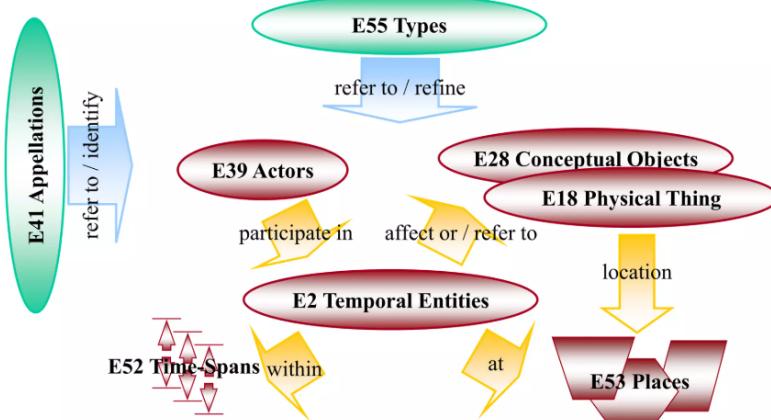

Figure 2.14: Fundamental concepts of ISO 21127 [10]

data from archaeological and museum collections, it has limitations in representing the characteristics of digital 3D artefacts.

2.6 Cultural Heritage Cloud

The European Collaborative Cloud for Cultural Heritage (ECCCH)²⁰ is a European Union initiative to create a shared digital infrastructure that connects CH institutions and professionals across the EU. The ECCCH introduces a digital dimension to the preservation, conservation, restoration, and enhancement of CH. It provides access to data from all over Europe, supports research, and pretends to increase the value of CH through digital representations of CH artefacts. In Portugal, the International Council of Museums (ICOM)²¹ is a beneficiary of the initiative, while Conference of Rectors of South-Western European Universities (CRUSOE)²² is an ECCCH association partner. CRUSOE is a university association comprising institutions from both Portugal and Spain. While ICOM Portugal and CRUSOE represent the participants in Portugal, the ECCCH also includes other 14 countries' beneficiaries, affiliated entities and/or associated partners across Europe that actively support those CH sectors enumerated above.

2.7 Discussion

The theoretical concepts introduced in this chapter provided the theoretical basis for the practical implementation described in Chapter 5. In particular, the principles of DCH, interaction and visualization techniques, input/output devices, and 3D reconstruction methods affect the implementation of the developed VE. This work utilized a VR environment that integrated various components to produce an immersive and interactive

²⁰<https://www.echoes-eccch.eu/>

²¹<https://icom-portugal.org/>

²²<https://redcrusoe.com/>

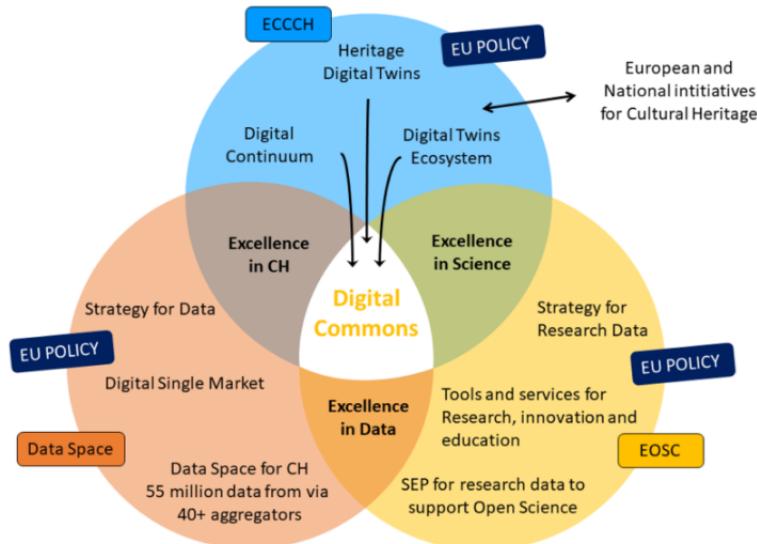

Figure 2.15: ECHOES goals 20.

experience. This includes the use of digital representations such as 3D models of glass artefacts and static images of the Troia ruins.

This dissertation is strongly grounded in the concept of DCH, understood as the digital representation of cultural assets in forms such as images, texts, and 3D models (Figure 2.2). Within this context, the DT emerges as a highly relevant paradigm, offering a dynamic way to mirror physical artefacts and environments.

Interaction and visualization techniques, such as ray-based selection and menu-driven interface (Figure 2.3), were essential to user engagement. These techniques allowed users to manipulate objects, navigate menus, and interact with the VE intuitively. While manipulation was limited to rotation and positioning, excluding transformations such as scaling or zooming, the implemented interactions ensured that users could meaningfully engage with the artefacts. These interaction techniques depended directly on the input/output devices employed. Controllers served as the primary input device, supporting the four VE task categories outlined in Section 2.2.2.1: selection, manipulation, travel, and system control. For example, selection was used both to grasp artefacts and to interact with User Interface (UI) elements; travel was enabled through teleportation and continuous locomotion; and system control allowed users to position objects in the environment when released. The *Meta Quest 3* headset, regarding the ones studied in this chapter, was the modern output device used, with a high-quality immersive display crucial for user testing.

Photogrammetry was applied to generate 3D models of glass artefacts and the funerary enclosure. Although LiDAR scanning was not explored due to time constraints, it remains a possibility for future developments. Artefact reconstruction also played a significant role, with specialists producing 2D documentation of interventions such as cleaning and restoration. These reconstructed elements can be explored in digital analysis.

The project integrated a database to organize object data, including identifiers, locations, functions, and conservation states. While geospatial data storage was prepared with Postgres' "location" table, it was not yet applied in practice due to time constraints. Nevertheless, the system was deliberately designed for scalability, ensuring compatibility with future enhancements. Standards and documentation, although only briefly considered, remain essential for ensuring the long-term sustainability of cultural heritage digitization.

This way, the dissertation not only contributes to the field of DCH but also aligns with European initiatives such as the ECCCH described in this chapter, which emphasizes the preservation, conservation, and dissemination of material cultural heritage. Moreover, while AR was not explored within this work, it is suggested as a direction for expanding into mixed reality in future developments, as discussed in Chapter [7](#).

RELATED WORK

This chapter presents research works that were considered related to this thesis theme. These studies were selected based on their relevance to the concepts described in Chapter 2, including Geographic Information System (GIS) integration, 3D modelling, spatial databases, and virtual tours.

3.1 The Turin 1911 Project

General Overview

The "Turin 1911: The World's Fair in Italy" is a research project [41] conducted by the *University of California San Diego* and *Politecnico di Torino* where a multidisciplinary team cooperates to document and investigate the 1911 World's Fair held in Turin. It integrates archival research, 3D reconstruction, and webGIS technology to study and preserve the architectural and Cultural Heritage (CH) of the Fair¹.

Process Description

The webGIS and GIS-Building Information Modelling (BIM)² web apps are interactive tools to digitally navigate and query the environment. Three types of elements were used to create a 3D webGIS: polygonal feature class, multi-patch feature class, or 3D object.

The historical map of the *Valentino Park Fairground* was georeferenced and digitized, and a 2D/3D map interface was developed using ArcGIS Online³, allowing users to switch between views seamlessly. To develop the 3D models in the BIM-GIS Web App, not only, photographs of each object, but also, plans, elevations, and sections of some Built Environment Objects, were collected. Using technical drawings, 3D models were generated and compared with historical photographs. The final webGIS application, for

¹<https://arcg.is/1HfSqG>

²<https://www.autodesk.com/solutions/aec/bim>

³<https://www.arcgis.com/index.html>

both dimensions, was created using ArcGIS Experience Builder⁴ configurable widgets (Figure 3.1).

Interactive Features

Several tools were developed in the webGIS, including a search bar, an option for switching between a 2D map and a 3D scene, a layer list, a legend, navigation controls, filters, and pop-ups, allowing users to explore built environment objects. BIM was used for detailed 3D reconstruction of selected Fair pavilions (e.g., Pavilion of Siam), and to create an interactive 3D scene with those layers. The actual shape of *Valentino Park* was created from an aerial photogrammetric survey and processed in Agisoft Metashape⁵. Applications like Experience Builder enhanced interactivity, offering features like navigation and measurement tools, bookmarks, layer toggles, and camera orientation. The current geolocation feature enables users in the park locate themselves on the webGIS and web app. The digitized archival materials are catalogued and linked to the geometries in a dedicated Geospatial Database.

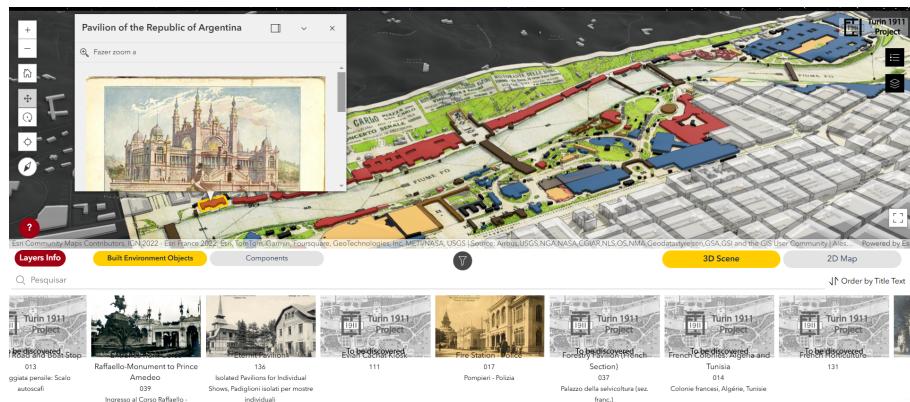

Figure 3.1: The webGIS application. Displayed functionalities: bottom left – search bar and objects list; top left – navigation controls and a pop-up; bottom right – 3D scene/2D map buttons; top right – map legend and layer control buttons.

3.2 Web-Based GIS for CH of Safranbolu, Turkey

General Overview

This study [2] focuses on the documentation and preservation of the CH of Safranbolu, Turkey, a UNESCO World Heritage site⁶. The goal of this project is to establish an internet-based information system and the modelling for GIS of all historical constructions of Safranbolu historical city. This will be accomplished by compiling documentation and preservation of CH, using GIS, 3D models and digital photogrammetry.

⁴<https://www.esri.com/en-us/arcgis/products/arcgis-experience-builder/>

⁵<https://www.agisoft.com/>

⁶<https://whc.unesco.org/en/list/614/>

Process Description

The development of this work started with digital photogrammetry, where the objects coordinate system was defined, and control points marked on the ancient artefacts, and photographs of the antiquities taken.

Pictures then were transferred to computer and evaluated with photogrammetric software (*Photomodeler*⁷). Following this, the 3D modelling of the historical buildings was executed. 3D of the building were obtained using photos from photogrammetry taken from different views, and the object models were covered with different surface and image textures. GIS was used to analyse spatial objects, such as buildings constructed within parcels and roads. Land parcels were represented as polygons, while roads with polylines. The city map of Safranbolu was obtained in Computer-Aided Design (CAD)⁸ format, and then transferred to ArcGIS. This data was then evaluated in GIS by building a topological infrastructure. In the next phase of the project, all collected data—such as photos, videos, architectural drawings, and 3D and Virtual Reality Modeling Language (VRML) [6] models—related to the selected historical buildings was prepared.

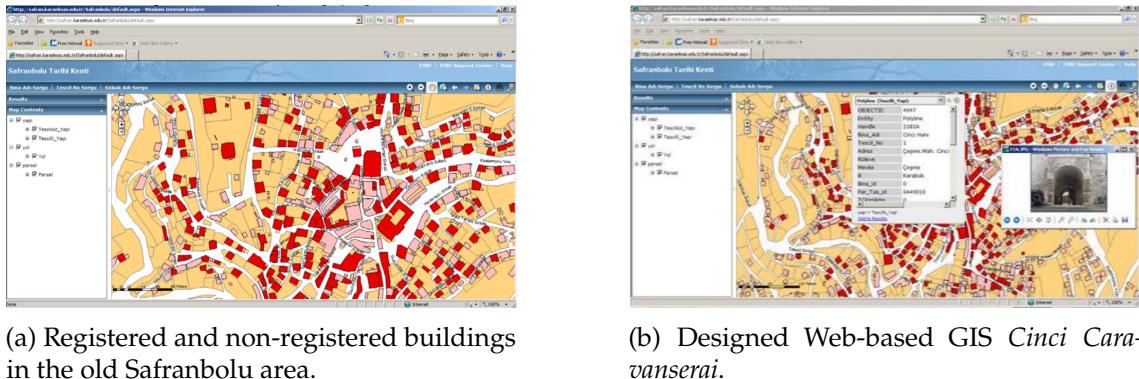

Figure 3.2: Illustrative views of the Web-GIS application.

This project integrates spatial data (e.g., building locations and 3D images) with non-spatial data (e.g., textual descriptions and historical information about the buildings) to document the historic town of Safranbolu. Through the interface (Figure 3.2), users can visualize various types of data, including land parcels, registered and non-registered buildings, roads, ownership details, addresses, and other relevant details about cultural monuments in the old Safranbolu area.

3.3 VR Scenario with Funerary Artifacts from Ancient Egypt

General Overview

This research [15] leverages VR to enhance the accessibility and understanding of Egyptian funerary artefacts in the Sforza Castle, Milan. Aimed at exhibition renewal, the project

⁷<https://www.photomodeler.com/>

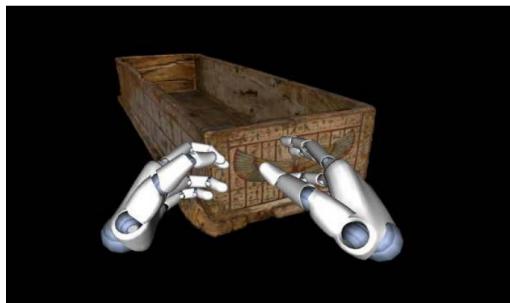

⁸<https://www.autodesk.com/pt/solutions/cad-software>

creates an immersive VR experience to engage visitors of the “Archaeological Museum” in Milan, with the ancient Egyptian “Path of the Dead” ritual, integrating interactive 3D models and hieroglyphic translation tools. Four key funerary artefacts were selected for their historical and archaeological significance: the Ushabty statuettes (representing a pharaoh or minister), the Heart Scarab amulet, and the Wooden Sarcophagus.

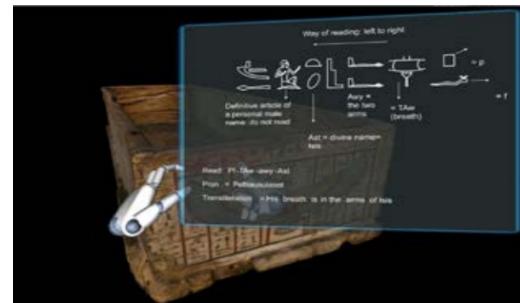

Process Description

Firstly, the photogrammetry survey was built by moving the camera all around these objects to capture all angles. Subsequently, the software *Agisoft Metashape* was used for texture blending. Then, the output file was imported into *Adobe Photoshop*⁹ for word delineation, outlining and identification. Finally, *Polyworks*¹⁰ was used to simplify the model, and in resolution/texture optimization. The VR device Oculus Rift DK2 provided stereoscopic visualization, while Leap Motion¹¹ tracked hand movements for object interaction (grabbing, rotating, and highlighting).

Responsive Points of Interest (POIs) created in the context of the project, were exported in *fbx*¹² format, and the cut parts of the artefacts were then imported to Unity¹³, for integration as 3D models. These POIs highlight cultural symbols and texts on artefacts (e.g., religious inscriptions). When selected, they provide detailed descriptions and explanations. The computer graphics program *3D Studio Max*¹⁴ was used to enhance specific elements of the models, to improve hieroglyphs readability. Touch-Triggered Transliteration and Translation allows users to interact with hieroglyphic symbols (Egyptian writing).

(a) Grabbing and rotating the object.

(b) Highlighting and translation the text.

Figure 3.3: Visual representations of the implemented VR scenario

If the user wants to know more about these words, they can touch them, and the word is automatically enhanced and the transliteration and the following translation appear as illustrated in Figure 3.3b. The data involved is the name of the deceased, and descriptions

explaining images or drawings on the objects. Users can rotate and grab the 3D models using hand gestures, as shown in Figure 3.3a.

3.4 Related Work developed at NOVA LINCS

At NOVA, recent research work has been consistently focused on developing digital tools for museums and cultural institutions, aiming to offer immersive experiences through VR technology or 3D media visualizations of CH objects, often incorporating interactive maps, an approach to be implemented in this dissertation. Over the past year, two Master of Science theses [7, 13] have explored how to present a virtual tour of museums. Vilar's thesis [45] explored interactive games and 3D models, with an emphasis on cultural artefacts from the Portuguese Évora site. The final thesis [5] focuses on 3D object manipulation, which may be integrated into this dissertation.

3.4.1 System for Creating and Exploring Interactive Narratives and Games

Vilar developed his research thesis work [45] as part of the PASEV¹⁵ Project Patrimonialization of Évora's Soundscape (PASEV). The main objective of the project was to analyse new perspectives regarding the cultural manifestations in UNESCO patrimonial city, Évora, which has a significant historical context [46]. The project started by Rosário [35] and was extended by Ferreira [14] which were mainly dedicated to the development of a historical soundscape's web platform¹⁶. This work focused on the study of sound events that occurred from 1540 to 1910 with the aim of preserving the city's auditory heritage [34]. The user can visualize and display audio and media(including, in some cases, 360° photos and videos) in the web platform.

Vilar expanded the existing PASEV platform by introducing JoNI, an infrastructure designed to support the creation of interactive games, involving motivational techniques, such as interactive narratives, gamification structures and the use of AR. In the end of this project, a mobile application was developed incorporating games with a narrative and characters, including 2D/3D models and auditory data, and object recognition via photos. Two functional prototypes supported by the platform were developed. The first, an interactive card game that teaches children about historical music instruments available at the Evora Museum¹⁷ using audio and visual elements. The second, a gamified app to promote the discovery of diverse locals with their itineraries. Along the route, textual content, videos, audios and a ranking progress are reproduced to generate an interactive and learnable experience. For each game, two main tabs were implemented for managing the map and AR features of the game.

This implementation includes AR and geolocation technologies to immerse users in Évora's CH. The solution was built on top of an existing base map. Afterward, the POIs

¹⁵<https://pasev.hcommons.org/>

¹⁶<https://pasev.uevora.pt/>

¹⁷<https://www.visitevora.net/en/evora-museum/>

of Évora were identified and represented with AR markers. Additionally, GPS tracking was integrated to allow users to monitor their location. The solution integrates a native Android environment and Unity game engine for seamless communication. The main goal of this dissertation is the dissemination of the CH and soundscape of Évora, with the solution integrated into Museu Nacional Frei Manuel do Cenáculo (MNFMC)¹⁸. The database was extended using PostgreSQL and PostGIS technologies.

3.4.2 Designing and implementing a museum Virtual Tour, Museu dos Coches

Coimbra [7] developed a VE that simulates a museum visit, providing an immersive and interactive user experience. The project integrates a 3D environment with 3D scanned objects, complemented by an intuitive and user-friendly interface. This virtual tour was based on the National Coach Museum¹⁹ and performs as a model for VR museum environments. This approach can revolutionize museum tours, suggesting an alternative, immersive, and innovative platform for cultural enrichment. The technologies used include Unity to create and deploy the VE, and the virtual visit requires a VR headset equipped with hand-tracking capabilities. For this purpose, the Meta Quest 3 Headset²⁰ was used to improve the processing power over earlier models. Therefore, this software ensures an optimized VR experience. Coimbra's thesis was developed in 2024 and has some points in common with this one. Both use digital tools for an interactive user experience with CH elements.

3.4.3 Web integration of virtual museums tours and 3D media visualization, Academia das Ciências

Last year, Faria [13] developed his dissertation work in collaboration with *Academia das Ciências de Lisboa*²¹, one of the oldest scientific institutions in Portugal, active since 1779. The academy is dedicated to promoting and preserving CH, with both physical and digital collections accessible to the public [1]. The project focuses on integrating CH objects in VEs. As part of this work, a website was created to provide a virtual tour of the academy, presenting its spaces and CH objects in an engaging and informative manner. This website is available at the following²². Designed with a user-friendly interface, the website offers an intuitive navigation experience, including an audio guide with simulated narration, background music, a 3D viewer, enabling the user to explore the components and history behind each artefact. The project also incorporates an interactive itinerary map, displaying all the available rooms and buttons for instinctive control of the tour. This feature allows

¹⁸<https://www.cm-evora.pt/locais/museu-nacional-frei-manuel-do-cenaculo/>

¹⁹<http://museudoscoches.gov.pt/>

²⁰<https://www.meta.com/quest/quest-3/>

²¹<https://www.acad-ciencias.pt/>

²²<https://visita3d.acad-ciencias.pt/>

users to explore the academy's diverse spaces quickly and effectively. Matterport²³ technology was employed to create the visualization and interaction environments, providing 3D spatial mapping of the academy's rooms. Complementing this, 3D object models were created and displayed in a Sketchfab²⁴ viewer. To support these features, several technologies were used, including Matterport Pro3 Camera²⁵ for the 3D scanning and 360° immersive views, along with frontend and backend frameworks, including Vue.js²⁶ and Tailwind CSS²⁷ for the interface, while the backend relied on Node.js²⁸. In addition, a database to store and manage the media content was implemented.

3.4.4 Developing support for digital representations of Heritage artefacts in cultural exhibitions

Campanha's thesis [5] aimed to extend the work of Nunes [29], by enhancing user interaction with artefacts in VE. The functionalities implemented in this work focus on object interaction, such as the ability to apply different textures, the possibility to manipulate specific parts of a 3D object independently, and access detailed information regarding these parts. Users can manipulate objects through the three axes (X,Y,Z) by rotating, scaling, or translating them within the virtual space. To obtain detailed information of the antiquities, the user simply selects the desired component. Additionally, users can upload the digital 3D representation of the object to the virtual exhibition and view a gallery menu displaying multiple perspectives of the 3D models associated with the same artefact. The system allows users to apply different textures to individual object components and select specific parts, which are outlined with their associated descriptions. The full interface, including these interactive features, can be observed below in Figure 3.4.

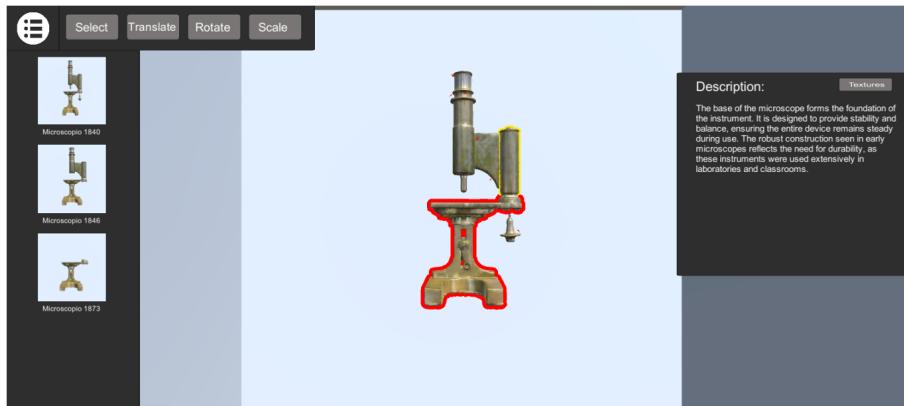

Figure 3.4: Interface for interacting with heritage artefacts.

3.5 Discussion

This section compares various recent research works and their relevance to this dissertation by analysing their components and contributions. Table 3.1 provides an illustration of these comparisons.

The "Turin 1911 Project" integrates an interactive map with multiple functionalities, while incorporating 3D models and a spatial database. Similarly, the Safranbolu GIS project focused on the preservation of an archaeological site, using 3D modeling to map historical buildings and integrating CH monuments as metadata relevant to the site. Both projects illustrate the use of 3D models and digital tools for documentation and preservation. However, while these studies remain primarily centered on mapping and geospatial analysis, other research has expanded the focus towards immersive VR visualization, as the following VR scenario study. The described project, integrated VR to provide an immersive environment, enabling users to interact with valuable artefacts from ancient Egypt. Features such as zooming, scaling, Egyptian writing translation, highlighting, and object manipulation were implemented to enhance the user experience.

To include contemporary Portuguese projects relevant to this research, Section 3.4 was added, exploring digital representations of cultural artefacts, and the dissemination of archeological sites and institutions. The following three projects integrate a virtual tour. Primarily, PASEV project extends an existing historical soundscape web platform by integrating AR. This work also incorporates 3D interactive models, a digital map, and was selected due to its completeness and the use of technologies, such as PostgreSQL and Unity, that were employed in this dissertation. Another relevant project is the National Coach Museum Tour, chosen for its VR development within a 3D environment. Similarly, the *Academia das Ciências* virtual tour provides an interactive experience by presenting 3D object models and integrating a spatial database. Additionally, an itinerary map of the Evora site and academy rooms allows transitions between the map and the VE, enabling users to virtually transport themselves to a specific academy room.

Finally, the last work provided an intuitive way to interact with 3D artefacts. This research developed a user interaction approach, allowing the manipulation with 3D object's individual components.

Table 3.1: Comparison of Projects Functionalities

Project Name	Interactive Map	3D Models Interaction	AR/VR Experience	Data Repository	Virtual Tour
Turin 1911 Project	✓	✓	✗	✗	✗
Safranbolu GIS	✓	✗	✗	✗	✗
VR Funerary Artifacts	✗	✓	✓	✗	✗
JoNI (PASEV)	✓	✓	✓	✓	✓
Museu dos Coches Virtual Tour	✗	✓	✗	✗	✓
Academia das Ciências 3D View	✗	✓	✗	✗	✓
Digital Representations of Heritage Artifacts	✗	✓	✓	✗	✗

We can conclude that there is a wide variety of approaches to the use of digital tools in CH. Among the projects analysed, the PASEV project appears to be the most comprehensive, integrating all the features considered, as illustrated in the Table 3.1. While an interactive map is included in this work, it remains at a preliminary stage compared to other features. Instead, priority was given to developing an immersive VR experience, which constitutes the main component of the system. The virtual tour is also present, but limited to a specific 3D model component. In general, most of the studied research works integrate only two of these features, highlighting the novelty of combining multiple approaches in this dissertation.

SYSTEM DESIGN

This chapter presents the overall design and conceptualization of the system developed. It begins in Section 4.1 with a description of the system requirements, followed by Section 4.2 that introduces the technologies and tools adopted. Subsequently, an overview of the system architecture is analysed in Section 4.3 and the database structure is presented in Section 4.4. Finally, it ends with a discussion of the implementation choices made, in Section 4.5.

4.1 Requirements

This section describes the requirements of this dissertation, categorized into the following areas: Interactive Map, 3D Model Interaction, and Virtual Reality (VR) environment.

Interactive Map

A map of the Troia archaeological site to offer interactive functionalities.

- **Map Navigation:** Users can navigate in the environment, and explore different locations.
- **Perspective Switching:** Toggle between top-down and profile views for better spatial understanding.
- **Layer Toggle:** Toggle visibility of layers, overlay a *.tif* map illustration, such as excavation campaigns.

3D Models & Interaction

A focus on the interaction with 3D models, which are integrated into a VR environment.

- **Artifact Interaction:** Allows users to virtually manipulate the glass artefact models.
- **Contextual Overlay:** Display descriptive data about the artefact, such as its origin, period, and historical usage.

- **Reconstructed Models:** Showcase how artefacts would look originally (having in consideration characteristics such as: colourless glass, archaeological drawings and symmetry).
- **3D Models Integration:** The user can zoom the map to visualize the perspective of a specific 3D model.

VR Environment

VR functionalities to provide an intuitive User Experience (UX), enabling interaction with the VE through the use of Head-Mounted Displays (HMDs).

- **Immersive Experience:** VR allows users to immerse in a virtual tomb visit, enabling interaction with glass relics.
- **Device Accessibility:** Primarily user-friendly and enabling haptic interaction, while supporting VR glasses as an emerging display option.
- **Localization & Wayfinding:**
 - **Points of Interest (POIs):** Use colors, text, visual markers, or direction arrows to emphasize and guide users to historically significant locations.

4.2 Adopted Tools and Tecnholoiges

The following section focuses on the technologies and tools used in implementing this project. These include environments used, Unity engine, development tools, backend, and data management.

4.2.1 Working Environment

The VR environment was developed using the Unity editor, with code scripts written in C# within the **Visual Studio Integrated Development Environment (IDE)**¹. Its features, such as debugging tools, error detection, code navigation, Unity-specific types recognized automatically, and IntelliSense suggestions, greatly enhanced productivity. To further support this integration, the Visual Studio Editor package was used.

For the backend implementation, comprising the Node.js server and the database, **Visual Studio Code (VSCode)**² was used.

The version control system used initially for project management was **GitHub**³, providing effective tracking of updates and overall code organization. However, as a consequence of storage limitations in handling large files, such as the 2D ground view or the funerary

¹<https://visualstudio.microsoft.com/>

²<https://code.visualstudio.com/>

³<https://github.com/>

enclosure 3D model, the **Diversion**⁴ tool was employed as an alternative solution for managing these system.

4.2.2 Unity

Unity is a cross-platform engine that provides a robust environment for developing 2D and 3D applications. Its component-based architecture simplifies 3D development by allowing developers to define object behaviors through scripts in Virtual Environments (VEs). Unity also offers a community forum and repositories available in **Unity Asset Store**⁵ where developers can access resources and adapt them for their projects.

For this study, Unity was selected for developing the VR environment. The C# programming language used within Unity facilitates the management of game objects and user interactions in the VE. Its integration enables users to have an immersive experience while interacting with the User Interface (UI), using the HMD. The headset device used for testing during the implementation and for user evaluation was **Meta Quest 3**.

4.2.2.1 Unity Packages and Plugins

This section comprises the main assets, plugins, and components used to support the custom implementation.

The following packages of Unity Asset Store were used to enhance the UI and streamline the development process:

- **Free UI Click Sound Pack**⁶ - This package provides a collection of diverse clickable sounds, designed to provide an immersive and complete UX.
- **Simple Pie Menu**⁷ - A radial menu system implemented as the main menu of the project. Further details on its functionality are provided in Section 5.2.1.
- **White & Black GUI**⁸ - This package includes a range of trivial and useful icons used to guide users in navigating menu items and to support image gallery switching between pre- and post-intervention object states.

The **Extended Reality (XR) Plugin Management** package was used to simplify the integration and management of various XR plug-ins. This package is primarily responsible for loading, initializing, configuring settings, and providing build support for XR features. It was used in conjunction with the OpenXR. **OpenXR** is an open-standard API enabling cross-platform development, with a high-performance access to AR and VR platforms and devices. In this study, this plugin handles communication with the VR headset.

⁷<https://assetstore.unity.com/packages/tools/gui/simple-pie-menu-radial-menu-asset-270056>

⁸<https://assetstore.unity.com/packages/2d/gui/icons/white-black-gui-by-gamertose-168805>

Diverse components of the **XR Interaction Toolkit**⁹ were integrated and added to the Unity Inspector, abstracting much of the low-level complexity of VR development. It enabled features such as Object interaction (grab and release), Teleportation-based locomotion, UI interaction, and Controller support. For interaction within the virtual scene, the **XR Near-far interactor** was added and provided a way to interact with the scene through the ray emitted from the controllers, and the **XR Grab Interactable** enabled direct manipulation of virtual objects through grabbing, holding, and releasing actions.

Its **XR Origin** structural component served as the root GameObject that encapsulated the main camera and controller setup. It handled camera tracking based on the user's head movement and managed controller positioning and orientation. Furthermore, to implement user movement within the VE, a Locomotion System was added with the following components integrated:

- **Continuous Move Provider:** Allowed smooth movement via the right joystick.
- **Snap Turn Provider:** Enabled rotational movement in fixed increments, chosen over continuous turning to reduce motion sickness.
- **Teleportation Provider:** Enabled teleportation across the plane surface using the left joystick.
- **Teleportation Anchors:** Defined specific teleportation points, represented as buttons.

For input handling, this toolkit provides two systems: the old Input Manager and the newer **Input System Package**. While the **Input Manager** is built into the Unity engine and used by default, the project adopted the Input System Package due to its flexibility and scalability. This newer system supports a wide range of input devices and enables precise configuration through a centralized interface. Input actions are defined and managed using the Input Action Manager, which allows the developer to specify actions and map them to devices or controls. Each input action is activated as needed during runtime, offering adaptable input handling.

4.2.3 Tools

Blender¹⁰ is an open-source computer graphics software useful to a wide range of tasks, such as model, animate, create textures, materials. This tool was used to create an approximation of the original texture of the glass object. Originally transparent, translucent.

GIMP¹¹, an open-source cross-platform image editor, was used to edit the map draw for integration as ground in Unity (rotated and cropped). Additionally, GIMP was useful in editing the post-intervention object images. The object's images were cut out from their

⁹<https://docs.unity3d.com/Packages/com.unity.xr.interaction.toolkit@3.0/manual/components.html>

¹⁰<https://www.blender.org/>

¹¹<https://www.gimp.org/>

backgrounds, which were then replaced with a neutral grey. This enhanced clarity for users and allowed easy comparison between the object's before and after the cleaning and conservation treatment.

4.2.3.1 Photogrammetry

The software used to process digital images and generate the 3D model of the funerary enclosure was *Agisoft Metashape*¹². This software performs photogrammetric processing of digital images to generate 3D spatial data, which can be applied in various fields such as GIS applications, CH documentation, visual effects production, and indirect measurements of objects of diverse scales.

A total of 143 images were collected after the excavation campaign by the archaeologist responsible for this site, Inês Vaz Pinto. Based on these images, a 3D model of the funerary enclosure was generated, as described in Section 5.3.4. As part of the collaboration with the institutions, two already built models of artefacts, were provided by Sofia Pires.

4.2.4 Backend & Data Management

This section includes the backend and database repository technologies choices.

4.2.4.1 Backend

The backend technology selected for this thesis was **Node.js**, an open-source, cross-platform JavaScript runtime environment. Node.js enables developers to create servers, web applications, command-line tools, and automation programs.

In this thesis, Node.js was used to support the web server and to improve performance and scalability when handling repository data. Additionally, it mediates the communication between Unity and the database repository.

Express.js¹³ is the most popular Node.js web application framework, widely used for building web applications and APIs, with a minimal and flexible design. In this study, the web server Express.js was used to expose the Representational State Transfer (REST)¹⁴ endpoints.

4.2.4.2 Database Repository

There are several alternatives for storage management systems, but the option selected for this project was **PostgreSQL** for its geographical extension, PostGIS, and its relational database is more appropriate due to its flexibility and consistency. Additionally, because of its high performance and flexibility in managing spatial data.

PostGIS is widely used for spatial data storage, geometry processing, and efficient geospatial data querying.

¹²<https://www.agisoft.com/>

¹³<https://expressjs.com/>

¹⁴<https://www.ibm.com/think/topics/rest-apis>

4.3 System Architecture

The system is divided into three application layers. The **Presentation Layer** manages the VR environment and its interaction with users. The **Application Layer** includes the management of Unity Requests, with the support of the framework "UnityWebRequest"¹⁵, acting as an intermediate between the Unity client and the database. The communication flow between these layers is managed through a Node.js REST API, chosen for its flexibility and lightweight design. Finally, the **Data Access Layer** contains the database, which stores all information related to object data, excavation, and object interventions. The architecture of the system can be observed in Figure 4.1.

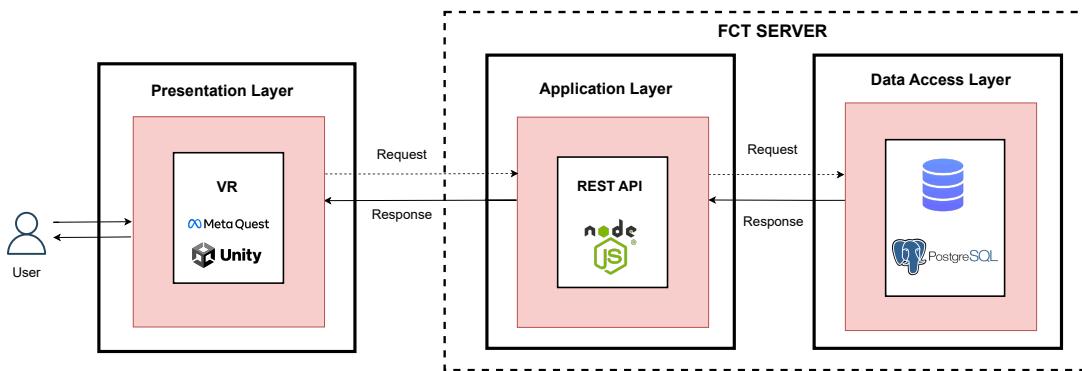

Figure 4.1: System Architecture Overview of the Developed System. © Ana Maissa Antunes

During the development stage, the database was hosted locally on a PostgreSQL server managed via pgAdmin¹⁶, an open source management tool for PostgreSQL. To access and present data in Unity, it was necessary to manually execute the "index.js" file, which contained the Node.js API endpoints. Subsequently, before the user testing phase, the code, comprising both the API endpoints and the PostgreSQL database, was deployed to the NOVA School of Science and Technology (FCT) Server with a dedicated service. This deployment ensured that the server hosting the API endpoints remained continuously active, allowing Unity clients to retrieve data seamlessly without manual intervention.

4.4 Database Structure

The database consists of 11 tables that ensure the significant data of excavation and objects are stored. The database model was designed considering future extensibility. Initially, it was structured to store significant data from the necropolis, including the funerary enclosure and tomb under study. The structure was generalized to improve scalability, flexibility to possibly include data, such as other tombs, associated objects, and aggregate

¹⁵ <https://docs.unity3d.com/6000.2/Documentation/ScriptReference/Networking.UnityWebRequest.html>

¹⁶ <https://www.pgadmin.org/>

the maximum information. Throughout the thesis period, the database structure was continuously refined and restructured with new tables, relations, and data fields.

It was decided not to store the entire object images as binary data in the database. Instead, only file paths to the images were saved. This allowed for efficient access and manipulation of images, while other object-related data, such as text and links, was fully stored in the database.

The entities of the database, along with their main attributes and relationships, are described below, representing the necropolis, funerary enclosures, tombs, objects, and excavation data. The `necropolis` table is the top-level table and contains general information about the site. The funerary enclosure or mausoleum is represented by the table `mausoleum`, which stores information such as `dimensions` and `construction_materials` and references the corresponding `id` in `necropolis`. The tomb within the mausoleum is represented by the table `tomb` and has a foreign key `id` referencing the associated mausoleum. While the `tomb_belonger` links tombs via its `id`. The table `object` stores all information of each object, with 27 attributes describing each artefact. Moreover, table `object_intervention` stores data about interventions performed by VICARTE, including `images_path_b_interv` and `images_path_a_interv`, representing images of the object before and after the intervention. This table references the `id` in the table `object`. Each object also has an associated table `location`, encompassing the coordinates of each object. Finally, the `excavation` contains excavation information, with two child tables: `excavation_protection` and `excavation_area`, inheriting the `id` of `excavation`.

In Unity, only the following attributes are retrieved and presented in the VR environment: from `object`, `id`, `name`, `material`, `provenance`, and `dimensions`; from `object_intervention`, `images_path_b_interv`, and `images_path_a_interv`.

The detailed structure, including relationships and attributes, is illustrated in Figure 4.2.

For generating the data model, SQL was used to create a database dump. Using "dbdiagram.io", this dump was translated into a visual diagram showing tables and their relations. This tool streamlined the creation of the Entity-Relationship diagram through code.

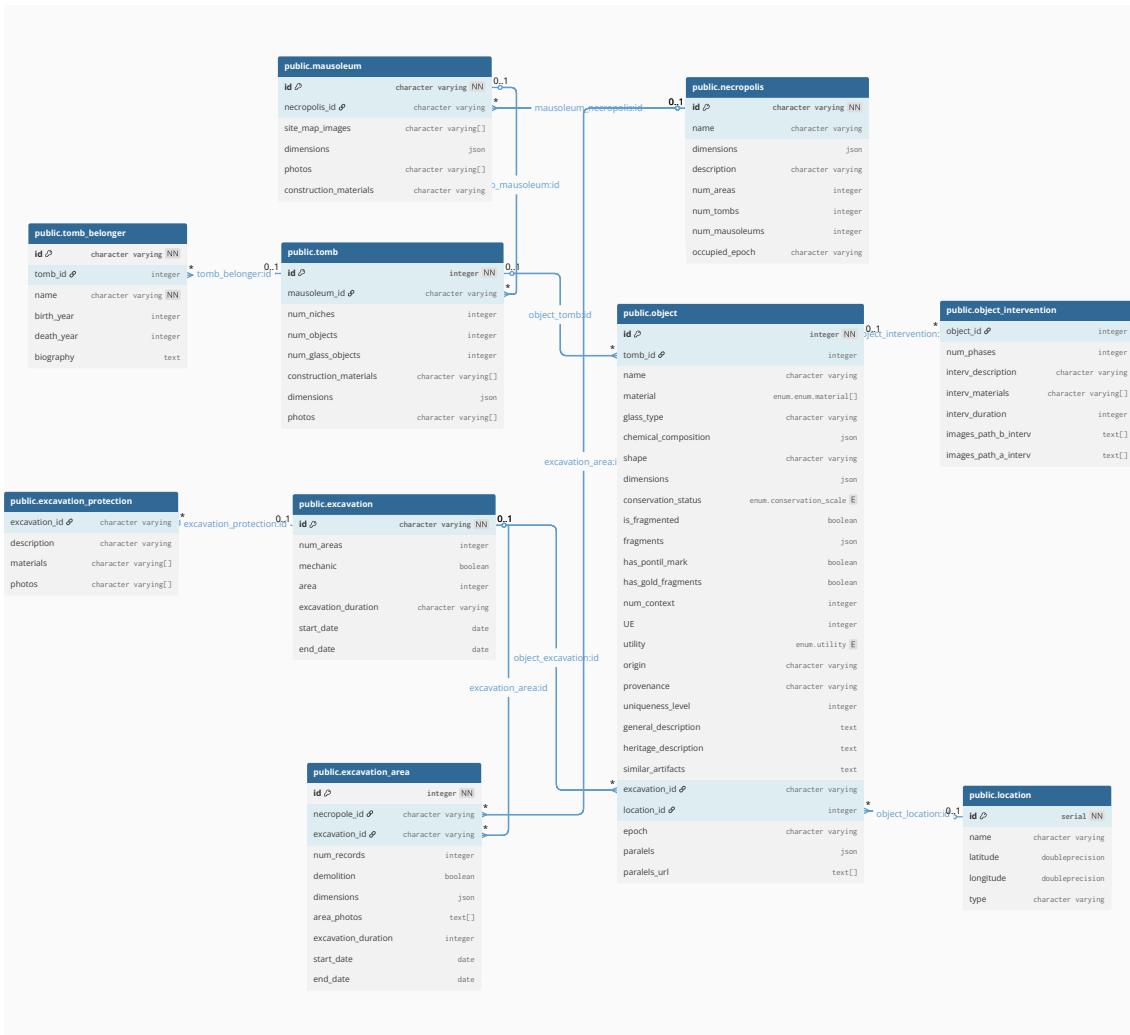

Figure 4.2: Relational Database Model.

4.5 Discussion

Given the diverse requirements of this project, the primary focus was on developing an immersive VE, prioritizing 3D models and VR functionalities for exploring glass artefacts within the tomb. Although interactive map features were included, they were implemented with a lower level of detail. At the beginning of the dissertation, the development of the VR environment and the database proceeded in parallel. Once the base database structure was implemented, the main focus was on the construction of the VE. The initial idea was to implement the map using JavaScript and the Leaflet.js¹⁷ library. However, the dissertation's direction shifted towards integrating the map with the funerary enclosure and its elements directly in Unity, forming a unified VE. This allowed users to walk across the map as if in reality, while simultaneously visualizing the 3D models accurately positioned in space.

¹⁷<https://leafletjs.com/>

IMPLEMENTATION DETAILS

This chapter begins in Section 5.1 with an explanation of the implementation connecting Unity requests to the database. The implementation process of all functionalities developed within the Virtual Environment (VE) is defined in Section 5.2. Then, the three fundamental techniques are described in detail in Section 5.3. Subsequently, Section 5.4 clarifies the testing and debugging methodologies applied during the dissertation. Finally, Section 5.5 resumes the implementation process.

5.1 Communication between Unity and Database

This section describes the process of connecting Unity to the database. The workflow proceeds as follows: Unity sends requests to the backend, which then forwards them to the database and returns the requested data to Unity. The first subsection presents the endpoints required to retrieve the necessary data, while the subsequent subsection details the specific requests made in Unity for data visualization.

5.1.1 API Endpoints

To retrieve information from the database for each object, requests are made to the repository layer. Two main API endpoints were implemented for this purpose:

1. /GET (get-objects_data)

Retrieves a list of object identification numbers (IDs) by querying the "object" table. These IDs are used to populate the dropdown menu options in the User Interface (UI).

2. /GET (get-objects_data/:id)

Fetches detailed information for a specific object based on its ID. This request is triggered when a user selects an object ID from the dropdown menu in the UI. Whenever the ID in the dropdown is changed, the system issues a new request for the corresponding ID, and the visualization panel and image gallery are updated accordingly.

Listing 5.1: Example of defining an API endpoint in Node.js.

```

1 //GET endpoint that retrieves object data by ID
2 app.get('/get-objects-data/:id', async (req, res) => {
3   const id = req.params.id;
4
5   try {
6     // Query to the database: select all object data present in 'object' and ,
7     // → 'object_intervention' tables
8     const result = await pool.query('SELECT * FROM object_inner JOIN
9       object_intervention ON object.id = object_intervention.object_id WHERE
10      object.id = $1', [id]);
11     res.json(result.rows[0]);
12   } catch (error) {
13     console.error(error);
14     res.status(500).send('Server_Error');
15   }
16 });

```

The representation of this endpoint is shown in Listing 5.1. As illustrated in line 6, the query joins two tables, "object" and "object_intervention", to fetch simultaneously object data and images before and after interventions for display in the Image Gallery feature. This SQL query enables the system to retrieve all necessary information with a single request after the user selects an object ID, thereby improving efficiency and reducing the need for multiple requests.

5.1.2 Unity requests to the Backend

The **UnityWebRequest** class was used to send HTTP requests to the Node.js server, supporting both options retrieval (Section 5.1.2.1) and object data retrieval (Section 5.1.2.2).

To acquire the desired data retrieval, only three data structures were required:

1. **Artifact** – representing an individual artefact and containing all attributes from the **artifact** table described in Chapter 4, Section 4.4.
2. **Dimensions** – a substructure of **Artifact**, storing three measurements: weight, height, and width.
3. **Artifact List** – a collection of **Artifact** structures to manage multiple objects retrieved from the database.

5.1.2.1 Dropdown Options Retrieval

This implementation retrieves all the IDs of the available artefacts, to fulfill the requirement of the user to view the desired object's textual and image information. The artefacts returned from the database are stored in a list structure, which is then iterated to populate the dropdown options list, as illustrated in Listing 5.2.

Listing 5.2: Method used to load artefact IDs and define as options in the Dropdown.

```
1  IEnumarator GetOptionsIds(string url)
2  {
3      // Send HTTP GET request to the given URL
4      UnityWebRequest www = UnityWebRequest.Get(url);
5      ...
6      if (www.result == UnityWebRequest.Result.Success)
7      {
8          ArtifactList artifactList = JsonUtility.FromJson<ArtifactList>(wrappedJson);
9
10         List<TMP_Dropdown.OptionData> options = new List<TMP_Dropdown.OptionData>();
11         ...
12         // Iterate through all artifacts and add their IDs to options List
13         foreach (Artifact artifact in artifactList.items)
14         {
15             string id = artifact.id.ToString();
16             options.Add(new TMP_Dropdown.OptionData("_____ " + id));
17         }
18         dropdown.AddOptions(options);
19     }
20     else{
21         Debug.LogError("Error: " + www.error);
22     }
23 }
```

5.1.2.2 Object Data Retrieval

This method, shown in Listing 5.3, retrieves all data of objects necessary to present in the VE. It sends a GET request to obtain the complete information, including images before and after objects intervention.

Additionally, textual data is retrieved. Once the request is successful, the JSON response is parsed into an `Artifact` object using Unity's `JsonUtility.FromJson<Artifact>()` method. From this structure, the following relevant fields are extracted: *id*, *name*, *material*, *epoch*, *provenance*, and *dimensions*. The *dimensions* field is a nested JSON structure containing *height*, *width*, and *weight*.

Finally, a formatted string is created to display the object's details in the UI panel functionality.

5.2 Virtual Environment

The initial step was to place the 2D map on the ground plane, using the 1-meter default grid scale of Unity to ensure the precise real-world dimensions. With this in place, it was only necessary to adjust the scale of the funerary enclosure to match its position on the map. It is also important to mention that the two objects in the environment were carefully measured using virtual rules.

In the VE, a set of functionalities was implemented. They are described in this section, in the following order: the Main Menu in Section 5.2.1, the Panel UI in Section 5.2.2, and

Listing 5.3: Method used to load object data from the database

```

1  IEnumerator GetData(string url)
2  {
3      if (www.result == UnityWebRequest.Result.Success)
4      {
5          artifact = JsonUtility.FromJson<Artifact>(www.downloadHandler.text);
6
7          string displayText = "<b>Object Details:</b>\n\n";
8          // Build the final text with detailed artifact information
9          displayText += $"ID:{artifact.id}|Name:{artifact.name}\nMaterial:{{
10              artifact.material}|Epoch:{artifact.epoch}\nProvenance:{artifact.
11              provenance}" +
12              $"\\nDimensions:{artifact.dimensions.height},x,{artifact.dimensions.
13                  width}cm,Weight:{Mathf.Round(artifact.dimensions.weight*_
14                  10.0f)*0.1f}g";
15          // Update the UI Panel with the artifact text details
16          resultText.text = displayText;
17          // Call the function to load images before intervention of the artifact
18          GetImages(artifact.id, artifact.images_path_b_interv);
19      }
20      ...
21  }

```

Points of Interest (POIs) in Section 5.2.3. Furthermore, funerary interaction is described in Section 5.2.5, and navigation logic in Sections 5.2.6 and 5.2.7.

5.2.1 Main Menu

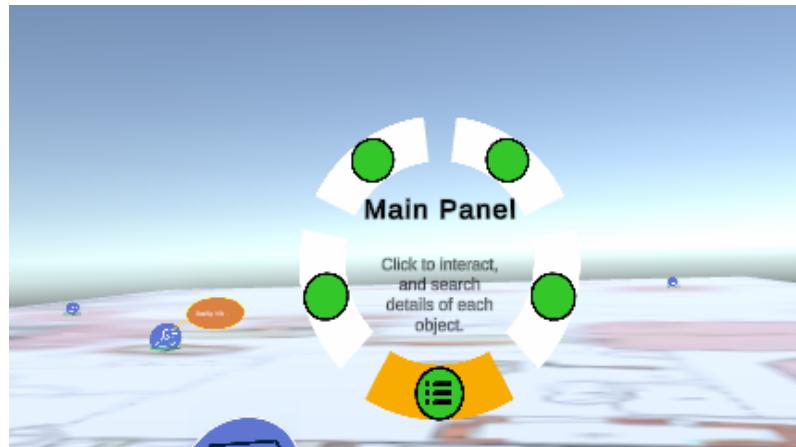

Figure 5.1: Main Menu Interaction, with the option of the Main Panel selected.

The main menu, displayed in Figure 5.1, was built with the support of the **SimplePieMenu** asset. However, it was restructured and adapted for use with VR controllers, since the original implementation was developed for Unity 3D without VR handling. The menu can be opened or closed with the trigger button of the right controller. The menu follows the user through the position of the right controller attributed in the "Follow_Controller" script. Additionally, to select an option, the user points at it with the ray

Listing 5.4: Method used to acquire the position that was pointed at by the controller ray.

```

1 public Vector2 GetPosition(Vector2 anchoredPosition, Transform controllerTransform)
2 {
3     // Create a ray starting from the controller's position, pointing forward
4     Ray ray = new Ray(controllerTransform.position, controllerTransform.forward);
5     /Raycast to detect collisions with the main menu
6     if (Physics.Raycast(ray, out RaycastHit hit, 50f, LayerMask.GetMask("Default")))
7     {
8         Vector3 screenPoint = Camera.main.WorldToScreenPoint(hit.point);
9
10        // Return the point relative to the center of the screen
11        return new Vector2(
12            screenPoint.x - Screen.width / 2f,
13            screenPoint.y - Screen.height / 2f);
14    }
15    return Vector2.zero;
16 }
```

and selects it using the right controller's select button. To detect which menu option is being targeted, a **Raycast** operation is performed based on the current position of the right controller ray, as illustrated in Listing 5.4.

Currently, the menu contains only one functional option, represented by a menu icon. This option performs a single action: activating or deactivating the **Panel UI** menu.

5.2.2 Panel UI

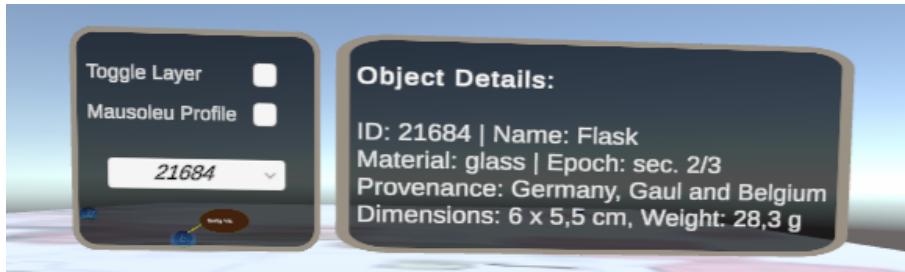

Figure 5.2: Panel UI Interaction.

The UI includes a canvas where users can interact with and explore object data, as shown in the left panel of Figure 5.2.

In this example, the object ID selected from the dropdown menu is "21684," and the textual data associated with this object is displayed in the right panel. This panel is initially empty and populates with the relevant object details after a selection is made.

The UI contains three interactive elements: the "Toggle Layer" and "Mausoleum Profile" checkboxes, and the "Dropdown Menu".

The first element, **Toggle Layer**, is a checkbox that controls the visibility of the ground plane. By default, the base plan is represented by a partial drawing of this archaeological site, which includes the burial enclosure under study. When the user activates the

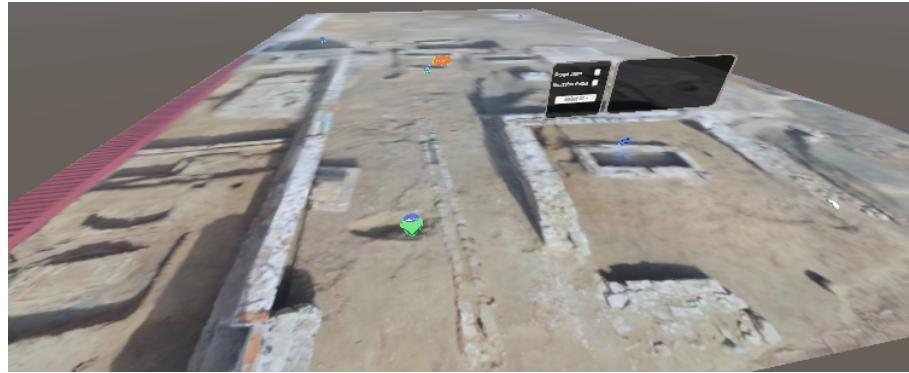

Figure 5.3: Toggle Layer to a photo of the Site Occidental part.

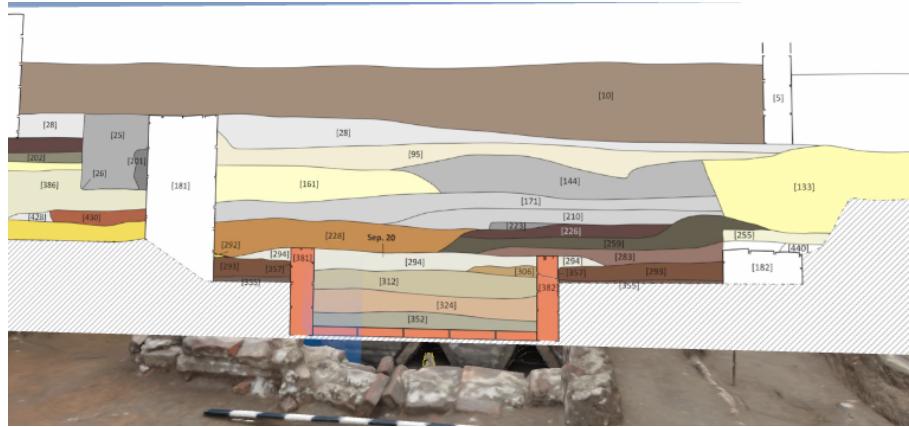

Figure 5.4: Funerary Enclosure Profile constructions layer view.

checkbox, the plan switches to a photograph of the actual site, offering a more realistic view and a stronger sense of presence. This feature is illustrated in Figure 5.3. The user can at any time toggle the view in the checkbox to view the pretended plan.

The second element, the **Funerary Enclosure Profile**, demonstrated in Figure 5.4, works similarly. However, in this case, it opens a profile image of the mausoleum wall, displaying the different material types and layers of construction.

The third element, the **Dropdown Menu**, allows the user to select an object by its ID. Once selected, the corresponding textual data and intervention images (Image Gallery) are retrieved from the database. The Image Gallery is displayed on the left, while the right side presents the textual data corresponding to the selected Object ID.

5.2.2.1 Image Gallery

The image gallery, as mentioned, is activated upon object selection. This gallery displays images of the object before and after intervention. Users can switch between these states by hovering the controller ray over the gallery arrow. In this manner, they can view the images of a concrete object, compare the visual differences, and acquire a clearer understanding of the intervention's impact on each object.

The implementation was made through a `GetImages` method that iterates over the

Figure 5.5: Image Gallery with object images before intervention.

array of image paths retrieved from the "object_intervention" table. The array passed to this method may be either "images_path_b_interv", containing the object images before intervention, or "images_path_a_interv", after the intervention. For each image, a component is created and positioned appropriately within the gallery. The process is presented in Listing 5.5.

5.2.3 Points of Interest (POIs)

Figure 5.6: Exemplified point of interest with an aggregated tooltip.

Diverse POIs were placed in key areas across the plane.

Users can teleport directly to a point of interest by selecting a blue anchor (implemented with the default *Teleportation Anchor* component) within the plan. These points are designed to draw the user's attention to notable features or artefacts, with the most

Listing 5.5: Method used to load artefact images and to display them in the Images Gallery.

```

1  private void GetImages(int id, string[] images_path)
2  {
3      if (images_path.Length != 0)
4      {
5          changeView.SetActive(true); // Enable the Image Gallery switching images
6          for (int x = 0; x < images_path.Length; x++) // Loop through all image paths
7          {
8              var imagePath = images_path[x]; // Get the current image path
9
10             // Load the image stored in the Resources folder
11             Sprite sprite = Resources.Load<Sprite>("Images/" + imagePath);
12             if (sprite != null)
13             { // Create a new GameObject for each image
14                 GameObject newImgObj = new GameObject("Image_" + imagePath, typeof(
15                     RectTransform), typeof(CanvasRenderer), typeof(Image));
16                 newImgObj.transform.SetParent(imageParent, false);
17
18                 // Configure the Gallery size and position
19                 RectTransform rectTransform = newImgObj.GetComponent<RectTransform>();
20                 rectTransform.sizeDelta = new Vector2(1, 1);
21                 rectTransform.localPosition = new Vector3(x_pos++, height, 0);
22
23                 Image imgComponent = newImgObj.GetComponent<Image>();
24                 imgComponent.sprite = sprite; // Assign the loaded image sprite
25                 ...
26             }
27         }
28     }

```

relevant point for the current study located inside the tomb within the funerary enclosure. Figure 5.6 illustrates one of these anchors.

In the future, the idea is to expand to other points and create interactive features as the 3D funerary enclosure model.

5.2.4 Object Interaction

This section describes object interaction, starting with the Slider in Section 5.2.4.1, the Outline in Section 5.2.4.2, and Grab and Release in Section 5.2.4.3

5.2.4.1 Object Slider

The Object Slider was designed as an interactive feature within the VE, allowing users to visualize an object's transformation over time, from its original condition to its current, restored state.

This functionality is illustrated in Figure 5.7, where the user holds the object with the left controller while manipulating the slider, named "Original Texture", with the right controller. The texture initially displayed corresponds to the post-excavation state, and as the user moves the slider to the right, it gradually transitions to the original glass texture.

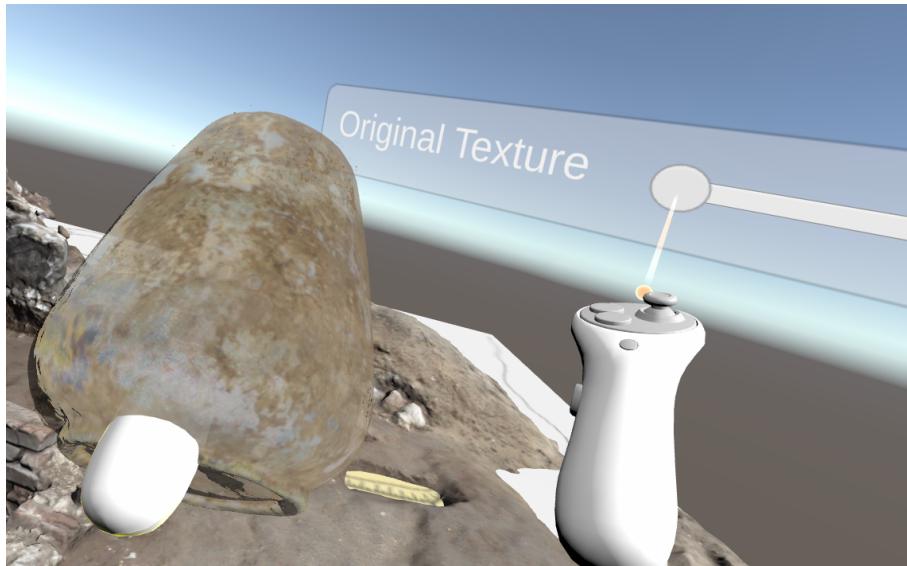

Figure 5.7: Object Slider Interaction.

The goal was to provide an immersive experience, creating the sensation of traveling back in time to observe the physical changes the object has undergone throughout the years.

Several experimental approaches were conducted to achieve this effect, focusing on shader development. Two main approaches were explored, as described below:

The first attempt involved creating a shader that utilized a single texture input, specifically the texture of the object after restoration. A white color was used to control the alpha (transparency) values, and the transition effect was managed using a linear interpolation (lerp) function. This shader was developed using Unity's Shader Graph, which provided a visual, node-based interface for building the transition logic.

The final solution involved a more advanced shader, written in Unity High-Level Shader Language (HLSL) for the Universal Render Pipeline (URP)¹. This approach provided more control over the material's appearance compared to Unity's built-in shaders. The shader was constructed using key URP shader libraries, including those for lighting and shading calculations², reflection probes³, shadow integration⁴, camera operations⁵, and transformations⁶.

This version accepted two texture inputs: the original appearance of the object (input variable `_DecayTex`) and its current state (input variable `_RestoredTex`). Besides the texture inputs, the shader provides the following adjustable material properties: *Blend Factor*, *Smoothness*, *Fresnel Power*, *Specular Color*, and *Reflection Intensity*, enabling precise

Listing 5.6: Partial Fragment shader for blending original and restored textures.

```

1 half4 frag(Varyings IN) : SV_Target
2 {
3     // Read the decay (original) texture restored texture at the UV coordinates
4     half4 decayAlbedo = SAMPLE_TEXTURE2D(_DecayTex, sampler_DecayTex, IN.uv);
5     half4 restoredAlbedo = SAMPLE_TEXTURE2D(_RestoredTex, sampler_RestoredTex, IN.uv);
6
7     // Normalize the world-space normal and view direction vectors
8     float3 normalWS = normalize(IN.worldNormal);
9     float3 viewDirWS = normalize(IN.viewDirWS);
10
11    float fresnel = CalculateFresnel(normalWS, viewDirWS, _FresnelPower);
12
13    // Blend attributes between decay and restored textures
14    half3 finalAlbedo = lerp(decayAlbedo.rgb, restoredAlbedo.rgb, _BlendFactor);
15    half finalAlpha = lerp(decayAlbedo.a, restoredAlbedo.a, _BlendFactor);
16    half finalSmoothness = lerp(_GlassSmoothness, _RestoredSmoothness, _BlendFactor);
17    ... Populate Data...
18
19    half3 glasslitColor = CalculateGlassLighting(surfaceData, inputData, fresnel);
20    half enhancedAlpha = lerp(finalAlpha, finalAlpha * 0.5, fresnel * 0.5);
21
22    // Return final color and alpha for the pixel
23    return half4(glasslitColor, enhancedAlpha);
24 }
```

control over how the textures blend and the visual appearance of the material. These properties can be modified directly through the Unity Inspector.

A **Lerp function**⁷ is a methodology that performs a linear interpolation between two values, based on an interpolation factor. In this case, it was used to interpolate between the two textures, considering their Albedo, Alpha, and Smoothness attributes, as shown in Listing 5.6. In this case, the interpolant factor is *_BlendFactor*, the input value that changes when the user moves the slider bar.

To enhance realism, additional lighting and reflection techniques were integrated into the shader, including the **Fresnel Effect**⁸ to model light behaviour based on the angle between the surface normal (*normalWS*) and the view direction (*viewDirWS*), and adjustments to **specular**, **diffuse**, and **environment lighting** properties. These calculations were performed independently for each component, as illustrated in Listing 5.7, before being aggregated into the final *finalColor*. This shader enabled a more faithful representation of the object's original appearance.

5.2.4.2 Object Outline

This functionality was implemented to improve the visibility of objects within the tomb and to distinguish them from the surrounding funerary ground. It essentially consists of

⁷<https://docs.unity3d.com/6000.2/Documentation/ScriptReference/Vector3.Lerp.html>

⁸<https://docs.unity3d.com/Packages/com.unity.shadergraph@6.9/manual/Fresnel-Effect-Node.html>

Listing 5.7: Lighting Glass Texture Partial Calculation.

```
1 float3 CalculateGlassLighting(SurfaceData surfaceData, InputData inputData, float fresnel)
2 {
3     // Compute independent calculations of main lighting, specular, defuse, and
4     // environment reflection.
5     Light mainLight = GetMainLight(inputData.shadowCoord, inputData.positionWS, inputData.
6         // shadowMask);
7     ...
8     float3 specular = specularTerm * mainLight.color * _SpecularColor.rgb * surfaceData.
9         // smoothness;
10    ...
11    float3 diffuse = lerp((surfaceData.albedo * mainLight.color * NdotL * 0.1), surfaceData.
12        // albedo, _BlendFactor);
13    ...
14    float3 environmentReflection = GlossyEnvironmentReflection(reflectionVector,
15        inputData.positionWS, surfaceData.smoothness, 1.0) * _ReflectionIntensity;
16    //Combine lighting contributions to produce the final color
17    float3 finalColor = diffuse + (specular + environmentReflection * fresnel);
18    return finalColor;
19 }
```

Figure 5.8: Outline effect applied when an object is hit with the controller ray.

an outline shader and a complementary script that manages its parameters. The shader highlights objects when targeted with the controller ray, as illustrated in Figure 5.8.

The shader includes the following input parameters: *Outline Color*, *Outline Width*, *Outline Power*, and *Outline Softness*. Similar to the shader described for the Object Slider functionality in Section 5.2.4.1, this shader also relies on the Fresnel effect to control outline intensity and appearance.

The rendering of each object includes two materials: a primary material representing its texture and a secondary material responsible for the outline effect. When the user

Listing 5.8: Partial class with Outline Color changed when the object is Hovered.

```

1  public class GlowingObject : MonoBehaviour
2  {
3      // Colors used for the outline: Yellow for default, Blue when hovered
4      ...
5      // Called to change outline color when the user starts hovering the object
6      public void OnHoverEnter()
7      {
8          meshRenderer.materials[1].SetColor("_OutlineColor", Blue);
9      }
10
11     public void OnHoverExit()
12     {
13         // Restore the default outline color
14         if(!select)
15             meshRenderer.materials[1].SetColor("_OutlineColor", Yellow);
16     }
17     ...
18 }
```

Listing 5.9: Partial Fragment shader for creating an outline effect to the object.

```

1 float4 frag(v2f i) : SV_Target
2 {
3     // Normalize the world-space normal (N) and view (V) direction vectors
4     ...
5     float fresnel = pow(1.0 - saturate(dot(N, V)), _OutlinePower);
6
7     // Define the inner and outer thresholds based on width and softness
8     float edge1 = 1.0 - _OutlineWidth;
9     float edge2 = edge1 + _OutlineSoftness;
10
11    //Interpolate the outline factor between edge1 and edge2
12    float outlineFactor = smoothstep(edge1, edge2, fresnel);
13
14    return _OutlineColor * outlineFactor;
15 }
```

points at the object, the parameter `OutlineColor` is switched from yellow to blue. But if the object is not being grabbed (`if(!select)`), the outline disappears. This behavior is handled through hover events, as shown in Listing 5.8. By accessing the second material of the object via `meshRenderer.materials[1]`, the shader updates the outline color.

The fragment shader logic for the glowing outline is presented in Listing 5.9. It computes the Fresnel term with the Outline Power attribute, and applies a `smoothstep()` to achieve a soft personalized outline. This mechanism ensures that the objects are easily identifiable.

5.2.4.3 Grab and Release Object

The artefacts can be grabbed with the lateral button of the controllers. When the object is grabbed or released, the corresponding event in Listing 5.10 is triggered.

Listing 5.10: Partial Fragment of objects onGrab and onRelease events.

```
1 private void OnGrab(SelectEventArgs args)
2 {
3     transform.localScale = zoomScale; // Zoom the object
4     // Disable all colliders
5     args.interactableObject.colliders.ForEach(collider =>{collider.enabled = false;});
6     ...
7     var interactor = args.interactorObject.transform;
8     // Adjust the slider bar position based on the controller
9     if (interactor.CompareTag("left"))
10    {
11        follow.targetOffset = new Vector3(sliderRightxPos, follow.targetOffset.y, follow.
12            ↪ targetOffset.z);
13    }
14    else if (interactor.CompareTag("right"))
15    {
16        follow.targetOffset = new Vector3(sliderLeftxPos, follow.targetOffset.y, follow.
17            ↪ targetOffset.z);
18    }
19 }
20 private void OnRelease(SelectEventArgs args)
21 {
22     transform.localScale = originalScale; // Restore the original scale
23
24     // Re-enable all colliders except if the user is inside the tomb
25     args.interactableObject.colliders.ForEach(collider =>{collider.enabled = true;});
26     if (r.isInsideTomb)
27     {
28         StartCoroutine(DisableColliderRoutine(5f));
29     }
30     ...
31 }
```

The proximity of the controller's ray to the object determines how close the object appears to the user's view. Releasing the object is achieved simply by releasing the button. Small objects are automatically zoomed when hovered over or grabbed (operation `transform.localScale = zoomScale`), improving clarity and visibility during interaction.

Additionally, two other behaviors are implemented. The colliders that might interfere during grabbing are reactivated upon release, except when the user is inside the tomb, in which case a coroutine (`StartCoroutine`) is executed. During `OnGrab`, and as illustrated in Figure 5.7, the object slider is repositioned depending on whether the object is grabbed with the left or right controller, controlled by the `CompareTag` method.

5.2.5 Funerary Enclosure Interaction

The system provides the possibility to activate or deactivate the 3D model of the funerary enclosure. This functionality is triggered using the trigger button of the left command. When the user points to the funerary enclosure area in the map, a purple reticle appears, indicating that the enclosure can be activated, as illustrated in Figure 5.9. This interaction

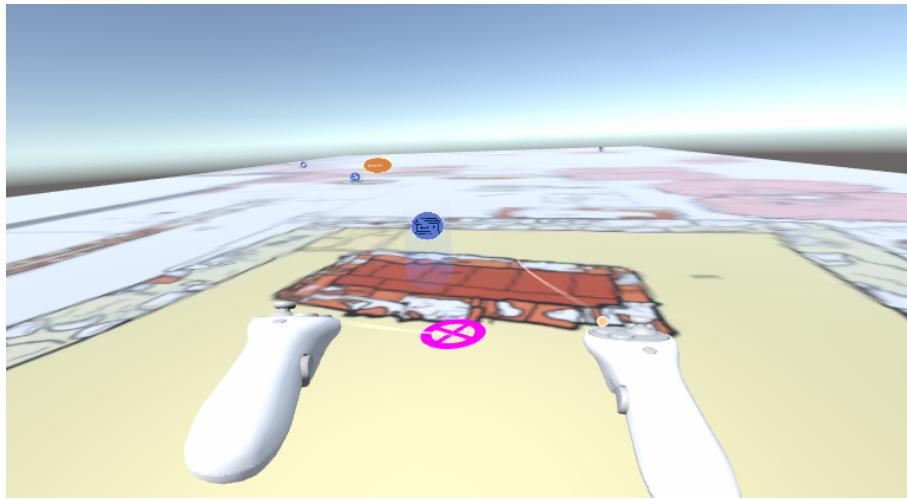

Figure 5.9: Funerary Enclosure Activation Reticle in the default ground plan.

can be performed at any point during the experience.

To ensure realism, the funerary enclosure is implemented with a default *Mesh Collider* combined with an aggregated *Rigidbody*. This configuration prevents the user from crossing the enclosure walls and accurately reproduces the surface levels of the original structure, thereby enhancing the immersive experience.

An exception occurs when the user is inside the tomb. In this case, the funerary enclosure collider is temporarily disabled, allowing the user to descend naturally to the ground without obstruction. Once the user exits the tomb, the collider is restored to maintain consistent collision detection.

5.2.6 User Navigation

The user can navigate in the environment with the controllers. These allow two modes of movement: continuous walking, which simulates real-world locomotion, and teleportation, providing a faster way to reposition within the scene.

There are two types of teleportation available in the environment. The first allows the user to teleport freely to any position on the environment's ground plane (default *Teleportation Area* component). The second restricts teleportation to specific POIs, marked with blue icons (anchors).

In addition to locomotion, users can switch their perspective inside the environment, using the controllers, moving laterally with the right joystick. Both continuous movement and snap turning can also be performed physically, without controllers, within the limits of the real-world space.

The overall movement system is managed by the *Character Controller* component, which also ensures accurate collision detection. In particular, the collider associated with the user interacts with the collider of the funerary enclosure, preventing the user from passing through walls and thereby preserving realism in the experience.

Listing 5.11: Recenter user position method.

```
1 void UpdateCharacterHeight()
2 { // Calculate camera position from world to local space
3     Vector3 center = transform.InverseTransformPoint(origin.Camera.transform.position);
4     // Update the character controller's center
5     character.center = new Vector3(center.x, center.y, center.z);
6 }
```

Listing 5.12: Apply costum gravity method.

```
1 private void ApplyCustomGravity()
2 {
3     Vector3 current = origin.Camera.transform.localPosition;
4     Vector3 delta = current - previousCamPos; // Movement since last frame
5     velocityY = delta.y;
6
7     if (character.isGrounded) // Check if user is currently touching the ground plan
8     {
9         velocityY = 0f;
10    }
11    else
12    { // Apply custom gravity
13        velocityY += Physics.gravity.y * Time.deltaTime * gravityMultiplier;
14    }
15    Vector3 move = new Vector3(delta.x, velocityY, delta.z);
16    character.Move(move * Time.deltaTime); // update user movement
17    previousCamPos = current; // update previous camera position for next frame
18 }
```

Further refinements and a dynamic management of movement behavior were introduced in the script "CustomMovement", where two key methods were implemented within Unity's default `Update()` function. The first method (Listing 5.11) continuously updates the center of the character controller to reflect the user's current position during locomotion. The second (Listing 5.12) manages custom movement behaviors by dynamically controlling gravity with `velocityY`. Depending on the context, gravity may either be applied or disabled. When active, it influences the user's velocity over time, and its intensity can be adjusted dynamically (`gravityMultiplier`).

5.2.7 Tomb Navigation Logic

To access the tomb, the user may either walk in continuous movement toward its interior or use teleportation by clicking on the blue anchor located in that area. Upon entering, the user will have a view similar to the one shown in Figure 5.11. The tomb contains triangular areas, that was the place where the majority of the objects were discovered. It's important to note that the artefacts are presented in the exact positions in which they were found during the excavations. During the dissertation process, different techniques were implemented and tested to address navigation and visualization challenges inside the tomb.

Figure 5.10: Tomb Exterior View with blue anchor inside.

Figure 5.11: Tomb Interior View with Objects positioned.

Plan Removal

The first approach used a collider placed inside the tomb. When the user collided with it, the ground plane was removed, revealing the full interior of the tomb.

This, in the end, caused conflicts because the interior collider overlapped with the collider responsible for activating the funerary enclosure.

To handle this issue, the limits of the tomb (coordinates x, y, and z) were defined manually. With this method, shown in Listing 5.13, the plane disappears when the user enters that space and reappears once the user exits it. In Figure 5.10, the outside view of the tomb is depicted. As illustrated, the plane is disabled, providing full visibility of the

Listing 5.13: Plan Removal approach in Update method().

```
1 void Update()
2 {
3     if (excavation_model.activeSelf) // Check if funerary model is active
4     {
5         if (camara.position.x >= x_min && camara.position.x <= x_max && camara.position.z
6             ↪ <= z_max && camara.position.z >= z_min && camara.position.y <= y_max &&
7             ↪ camara.position.y >= y_min)
8         {
9             if(toggle_UI.firstactive) // Deactivate the plan if inside the tomb area
10                plane.SetActive(false);
11            else plane2.SetActive(false);
12
13            if(camara.position.y <= plane.transform.position.y + 0.4f)
14                mausoleu.SetActive(false); //Disable mausoleum/funerary collider so the
15                ↪ user can fall inside the tomb without colliding
16            isInsideTomb = true;
17        }
18        else
19        {
20            if (toggle_UI.firstactive) // Reactivate the plan if outside the tomb area
21                plane.SetActive(true);
22            else
23                plane2.SetActive(true);
24            isInsideTomb = false;
25            mausoleu.SetActive(true); // Reactivate mausoleum collider
26        }
27    }
28 }
```

tomb's interior.

Vertical Descend

Another challenge was ensuring that users could navigate naturally within the tomb while maintaining clear visibility of objects and architectural details inside. Standard gravity alone was insufficient, as it did not allow reliable interaction with objects located in triangular areas. To address this, the "TombNavigation" script was developed, introducing controlled vertical displacement along the y-axis.

Initially, a Raycasting approach was tested, directing rays toward the front and the floor of the tomb. When a collision was detected, the user's position was adjusted and lowered by a few centimeters. Although functional, this method is unreliable, as it heavily depends on the user's viewing direction, extracted from the camera position.

The final implementation instead defined the tomb interior using axis-based boundaries (x, y, and z coordinates). When the user entered this delimited area, they were automatically replaced downward with the new_y factor. Upon exiting, the user's position was restored to its correct height (camPosbefore), ensuring they did not remain unnaturally below the expected level. This approach, represented in Listing 5.14 allows the user to enter and exit the tomb by simply walking.

Listing 5.14: Vertical Descend approach in Update method().

```

1 void Update()
2 {
3     var camara = Camera.main.transform;
4     if (!isInside && cam.transform.localPosition.y != new_y)
5     {
6         camPosbefore = cam.transform.localPosition; // Position before entering the tomb
7     }
8     if (!plane.activeSelf && camara.position.x >= x_min && camara.position.x <= x_max &&
9         ↪ camara.position.z <= z_max && camara.position.z >= z_min && camara.position.y
10        ↪ <= y_max && camara.position.y >= y_min) //check if position inside the tomb
11    {
12        isInside = true;
13        mausoleu.collider.SetActive(false); // Deactivate funerary collider
14        cam.transform.localPosition = new Vector3(cam.transform.localPosition.x, new_y, cam.
15            ↪ transform.localPosition.z); //User replaced to a lower position
16    }
17    else
18    {
19        isInside = false;
20        mausoleu.collider.SetActive(true); // Reactivate the funerary/mausoleum collider
21        cam.transform.localPosition = camPosbefore; // Reset the user's position
22    }
23 }
```

During development, two alternative exit mechanisms, a block and a ladder, were added. However, these were later deactivated, as they were unnecessary with the finalized gravity-based solution and occupied additional space in the relatively small tomb environment. Nevertheless, both alternatives remain available for reactivation if required in the future.

5.3 Key Techniques

This section describes the main techniques implemented during the development process. The first two techniques focus on optimizing User Experience (UX) and improving system performance by significantly reducing the complexity of the funerary model, while preserving essential detail. The last two techniques detail the methodologies used to generate the glass material and the funerary 3D model.

5.3.1 Light Technique

There is a main directional light that illuminates the entire environment, simulating reality. However, it was understood that depending on the angle, the user might see the tomb and objects as black due to shadows. To address this, a secondary point light was added that follows the user, so the user can view the tomb with clarity and have a good visibility while navigating in the environment.

5.3.2 Funerary Enclosure Model Reduction

The resolution of the burial site model was significantly reduced in *Agisoft Metashape* software through the "Decimate Model" property. This adjustment was necessary due to warnings of potential collision issues arising from the model's size of over 2 million triangles. Therefore, the number of faces was reduced from 1.9 million to approximately 100 thousand, preserving the essential level of detail while improving efficiency.

5.3.3 Generating the Glass Texture

The process of generating the glass texture consisted of two phases.

First, the material was modeled in Blender using a node-based shader structure. The desired glass effect was achieved by combining the Glossy BSDF and Refraction BSDF nodes. It also received a Fresnel node as input⁹. This structure is represented in Figure 5.12.

After having the node structure, a UV unwrapping¹⁰ was made to prepare the 3D object surface for texture mapping, process illustrated in Figure 5.13. Finally, a baking process¹¹ was performed using the Cycles render engine. With these materials, a "Combined" texture was baked and imported to Unity as a .png file.

In Unity, one **Reflection Probe** for each object was added to simulate the environment's reflection on the glass surface. Additionally, the four attributes *_GlassSmoothness*, *_FresnelPower*, *_SpecularColor*, and *_ReflectionIntensity*, used in the slider shader in Section 5.2.4.1, can be adjusted to control the pretended reflections in the glass. The final glass texture exemplifying one object is illustrated in Figure 5.14.

5.3.4 Generating the Funerary 3D Model

The funerary enclosure model was generated with the support of the photogrammetric survey and subsequently imported into the *Sketchfab* viewer for intuitive interaction. Within the grave, three open triangular areas were identified, containing the precious artefacts of the deceased, as shown in Figure 5.15 below.

This phase used the *Agisoft Metashape* to stitch together photographs and capture the geometry, texture, and visual characteristics of the physical funerary structure.

The workflow began with the Align Photos operation, which produced 91,053 tie points. Then, a dense point cloud was generated to refine the level of detail, followed by the creation of a 3D mesh. The resulting model comprised 1,910,026 faces, for which a texture was mapped. Finally, the model was exported in .obj format, and grouped with .png texture files, and imported into the Unity VR environment.

5.4 Testing and Debugging

One of the most relevant features during the development phase on controller support was the **XR Device Simulator** included in XR Interaction Toolkit. This utility allowed for testing VR interactions without the need for a physical Head-Mounted Display (HMD). It simulated input from VR controllers using a standard mouse and keyboard. Despite its usefulness in this dissertation, it's important to note that certain interactions did not

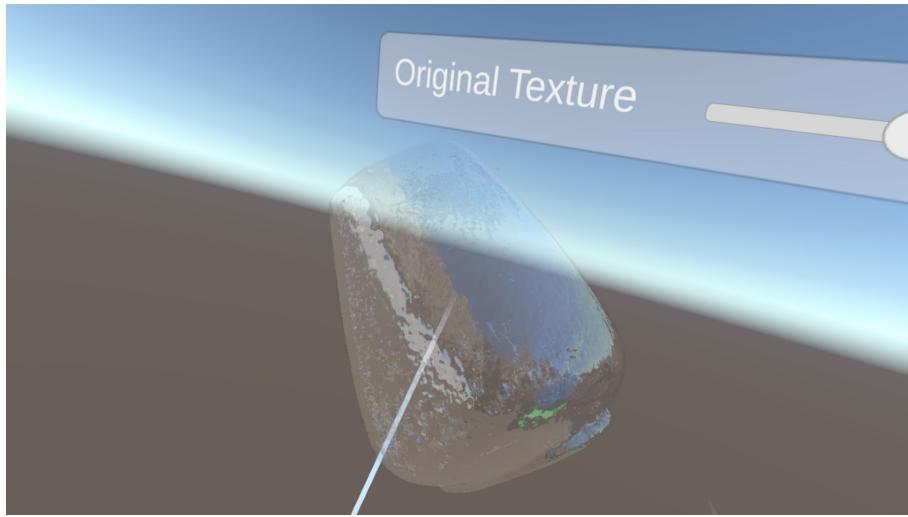

Figure 5.14: Glass Texture of Object with ID 21684.

Figure 5.15: 3D Model in Sketchfab.

behave identically compared to testing with the actual headset.

During development, the functionalities within the environment were tested in real-time using the *MetaLink* app. However, when connected via Wi-Fi, the environment did not load correctly. This issue was solved using a wired connection. Additionally, Debugging was performed with Visual Studio debugger and Android Debug Bridge (adb), which enabled in-depth troubleshooting and identification of headset interaction issues by accessing detailed system logs through the `adb logcat` command. The logs proved useful for tracing errors and understanding their source during testing.

5.5 Conclusions

The implementation began with generating the funerary enclosure model, which was later integrated into the Unity environment. The model was positioned on the map, and

functionalities such as 3D model visualization and map navigation were implemented according to the requirements outlined in Section 4.1. Users can grab objects and interact with a panel menu that displays data retrieved from the database. A dedicated database stores significant artefact and excavation data, updated as development progresses. For interaction inside the tomb, two glass objects were selected as the primary focus.

To enable communication between Unity and the database, a backend API was implemented. Unity sends requests to the backend, which then queries the database and returns the requested information. A *dropdown menu* was created in the VE to fulfill the "Contextual Overlay" requirement, allowing users to select an artefact ID and access the corresponding textual and visual data. This feature is supported by two request types: (i) retrieval of all available IDs from the "object" table, and (ii) retrieval of associated textual and image data, by combining information from the "object" and "object_intervention" tables. The layer toggle functionality integrates a photograph of the actual site, providing a stronger sense of presence for the user. The perspective switching feature utilizes an image of the funerary enclosure wall materials. For artefact reconstruction, a simplified approach was adopted: instead of reconstructing fragmented models, the system simulates the original object texture through the *Object Slider* functionality. The resulting implementation enables users to enter the tomb and experience an immersive interaction with two glass relics. Additional POIs were distributed across the map, enhancing the user experience. Finally, each functionality was tested individually, which facilitated the identification and correction of errors during development.

USER EVALUATION

This chapter describes the user evaluation conducted in the scope of this dissertation. Section 6.1 describes the methodology and procedures adopted for the evaluation, while Section 6.2 presents the results obtained from the questionnaires, including a description of each type of questionnaire used and its intended purpose. Finally, Section 6.3 provides a resume of the results and main conclusions from the evaluation, as well as the improvements implemented based on user feedback.

User testing was conducted in person with several groups of participants. VICARTE experts, archaeologists (including the director of the Roman Ruins of Troia), and regular users. This combination enabled comprehensive feedback. To differentiate and collect statistics from these groups independently, a question was added to the form to filter participants by professional specialty. In this context, testing with experts was particularly relevant, as these archaeologists were familiar with the site and had examined the actual objects. They contributed with their expertise in evaluating aspects such as the original glass texture generated (Section 5.3.3) and the tomb's 3D model (Section 5.3.4).

In total, 28 tests were carried out in person: 16 tests were executed with standard users, 3 with archaeologists, and 9 with VICARTE members, including conservation and restoration specialists. The last group provided essential technical feedback in this field, as they were directly involved in interventions with the real objects. The remaining users contributed a broader perspective on the usability of the Virtual Environment (VE). Colleagues with prior VR experience offered more informed insights, while standard users provided suggestions from a regular user's perspective.

6.1 Protocol

This section describes the protocol adopted for the user evaluation questionnaire, which was organized into five subsections of the user form, each with a brief description and the corresponding test results.

The tests were fundamental in evaluating the usability of the developed environment, as well as the sense of presence and the overall experience.

First, a brief introduction of the project was presented, followed by an explanation of the test structure. Before using the headset, the participants completed a personal questionnaire for statistical user analysis. Prior to the test, the usage of the controllers and main buttons was explained. Subsequently, the participants put on the Head-Mounted Display (HMD) and used the right and left controllers. Then, the users were asked to complete a set of predefined tasks for the experience, and were guided through this order:

1. Try walking in continuous motion and/or teleporting in the environment.
2. Activate the 3D model of the funerary enclosure.
3. Walk to the tomb or select its blue icon to teleport.
4. Inside the tomb, point at an object until you see its blue outline and grab it.
5. Exit the tomb with the object in your hand.
6. With the object in your hand, use the other controller to move the slider and view its original appearance.
7. Release the object by releasing the side button on the controller.
8. Teleport to a Point of Interest by selecting one of the blue icons.
9. Activate the main menu and select the visible icon.
10. Close the main menu.
11. In the panel in front of you, select the Object ID 21684 and view the displayed information.
12. Walk to the blue panel and hover over the arrows to view object images after the intervention.
13. In the black panel in front of you, change the ground plane by selecting the "Toggle Layer" option and explore.

After completing the tasks, users evaluated the experience through three segments of a Google Form. The first measured task success and the perception of key functionalities. The second assessed the sense of presence in the environment, and the third evaluated the overall experience.

All these questions, including the initial user profile and statistical analysis, as well as the segments addressing task difficulty, sense of presence, and overall experience, were part of the user questionnaire, whose full structure is presented in Appendix A.

While the users were wearing the HMD and controllers in their hands, as displayed in Figure 6.1, the set of tasks to perform was repeated to them, since the goal was not to evaluate memory, but usability.

Figure 6.1: User Testing the VR Environment with the HMD and controllers.

During the experience, the time each user spent interacting with the VR environment was recorded. As shown in Figure 6.2, the average duration to complete all tasks was around 10 minutes, with the exception of faster users and three cases where the application had to be restarted after users fell out of the environment, which increased the experience time. The exact completion times for each participant are presented in the Appendix B.

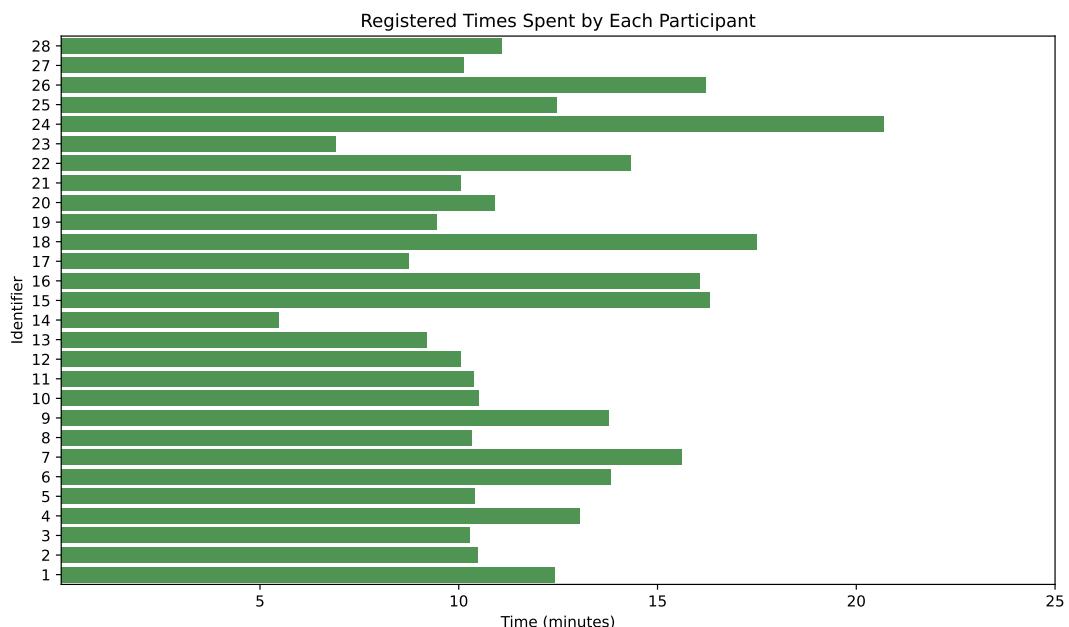

Figure 6.2: Registered Times spent by each Participant to Execute the provided Tasks.

6.1.1 User Testing Setup

To prepare the VR environment for user testing, an **Android build** was generated in Unity, producing an *.apk* file that allowed the application to run natively on the headset without requiring a cable. This increased flexibility during the evaluation. The *Meta Quest Developer Hub* application was then used to transfer the *.apk* file to the headset.

Before the evaluation, the headset was configured, and the "Meta Horizon"¹ mobile application was initialized to manage the headset. It provides access to the headset, including storage management, device settings, and the ability to cast the headset's view to a smartphone. By activating the "Cast" option, the researcher could mirror exactly what the user was seeing on the headset. This setup allowed users to be guided through the intended tasks and to receive immediate assistance if any issues arose.

6.2 Tests Results

This section is organized into five subsections to present and analyse the results. The first subsection, "User Analysis," presents statistical information about the participants. The second, "Tasks Difficulty and Feedback," reports their perceptions after completing the tasks. In addition, the PQ and User Experience Questionnaire (UEQ) were employed to evaluate the sense of presence and overall experience. Finally, the subsection "Participants Profile Comparison" provides graphical representations highlighting relevant relationships between the users and their responses after performing the tasks.

6.2.1 User Analysis

This questionnaire component was designed to collect information on users' characteristics, enabling the identification of statistical differences and supporting the interpretation of the evaluation results. It collects demographic data, including age, gender, and education, along with information on participants' professional or academic background. In addition, these questions assess prior experience with VR and digital technologies applied to CH.

The bar plot in Figure 6.3 illustrates the distribution of participants across age groups. A decreasing trend of users can be observed with increasing age. Notably, the majority of participants, 86%, are younger than 45 years old.

There is a balanced gender distribution as we can see in Figure 6.4.

In the pie chart of Figure 6.5, the educational degrees of the participants is depicted. The distribution indicates a predominance of higher education (bachelor, master, and doctorate degrees), whereas only a small proportion of participants reported lower levels of education.

In Figure 6.6, a horizontal bar plot illustrates the distribution of participants' technical backgrounds. The areas are ordered in descending frequency, with priority given to those

¹<https://horizon.meta.com/>

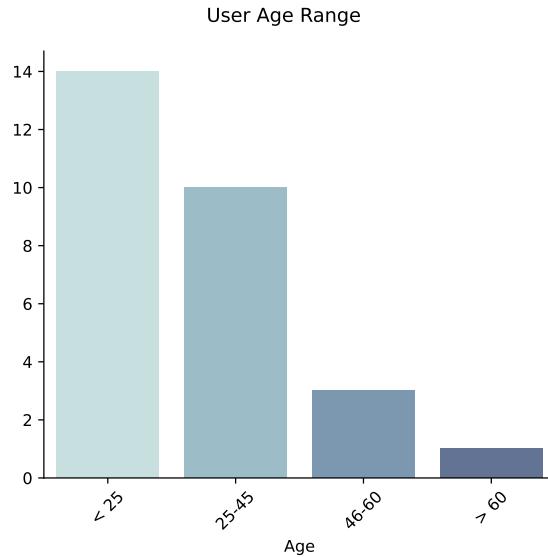

Figure 6.3: Age Distribution of the Test Participants.

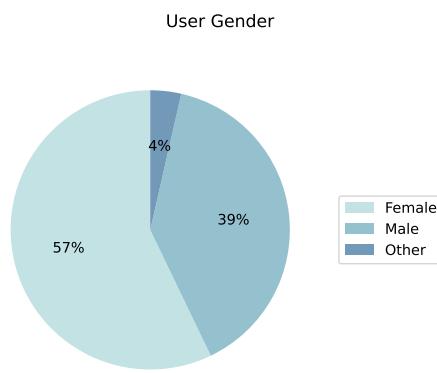

Figure 6.4: Gender Distribution of the Test Participants.

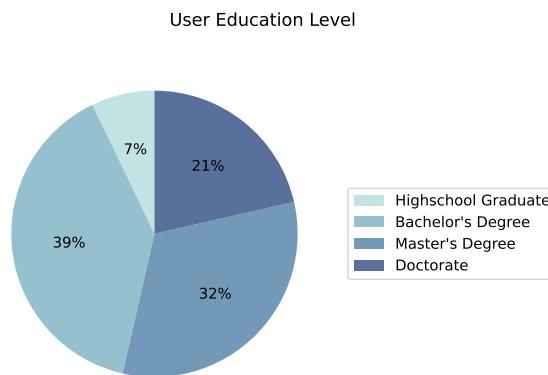

Figure 6.5: Education Level Distribution of the Test Participants.

most relevant for this thesis. This results in a meaningful sample, comprising mainly technology developers, specialists in conservation and restoration, and archaeologists

6.2. TESTS RESULTS

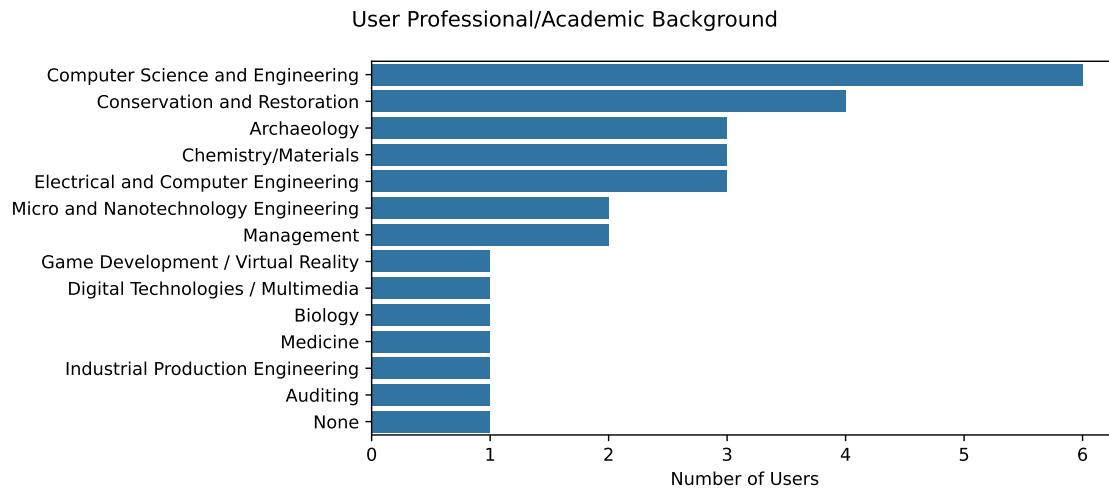

Figure 6.6: Distribution of Training Levels among Participants.

working in contexts related to the site under study.

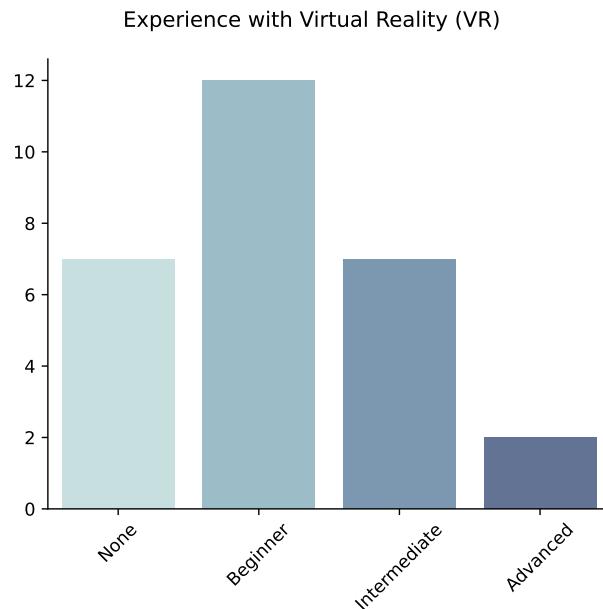

Figure 6.7: VR Experience Levels among Participants.

As illustrated in Figure 6.7, it is evident that the majority of the participants have prior experience with VR, while only a small portion consider themselves experts.

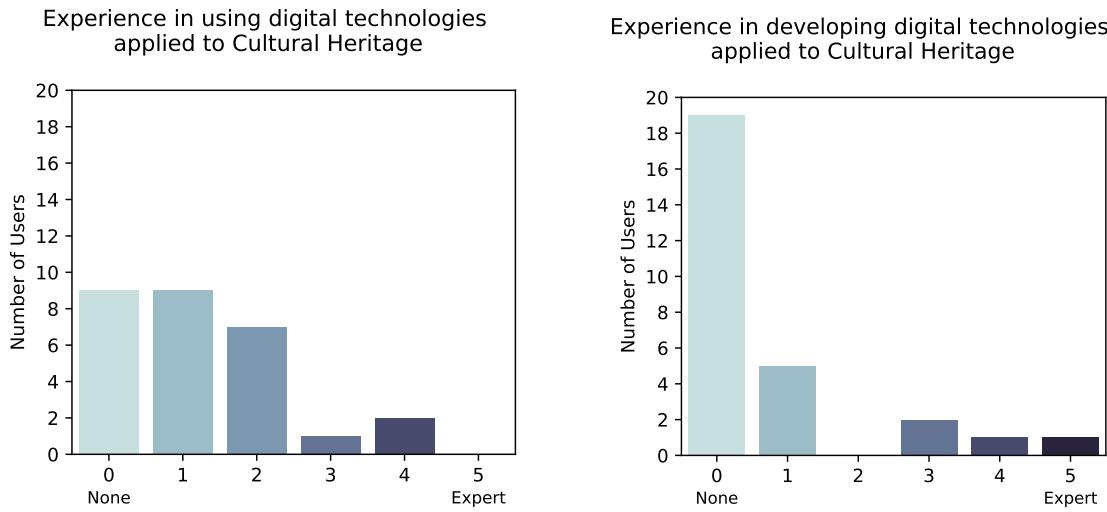

Figure 6.8: Participants' Experience with Digital Technologies Applied to CH.

The two distributions in Figure 6.8 show a clear disparity between participants' experiences in using and developing digital heritage technologies. Most participants (19) report having some experience as users, generally clustering around moderate levels (ratings 1–2). In contrast, almost all participants (19) report no development experience. For evaluation purposes, the key factor is the intended use of the system. Developers remain valuable mainly for offering technical feedback and suggestions for improvements, such as efficiency.

6.2.2 Tasks Difficulty and Feedback

This segment of questions was answered immediately after the users completed their tasks in the VE. The first question in this section used a 5-point Likert scale to measure the perceived difficulty of each task, providing insights that may support future improvements or adjustments to the UI. The second and final question in this section presented a list of ten statements, tailored to the evaluation of this environment, which users rated on a 5-point Likert scale according to their level of agreement. This helps to capture more specific perceptions regarding each relevant functionality and the overall experience within the environment.

The tasks represented in the graph correspond to the specific actions evaluated:

T1 – Viewing object's textual information

T2 – Viewing the image gallery

T3 – Grabbing and manipulating artifact

T4 – Access to the main menu

T5 – View object original appearance

T6 – Move around the environment

T7 – Access a point of interest

T8 – Change the base (ground) plan

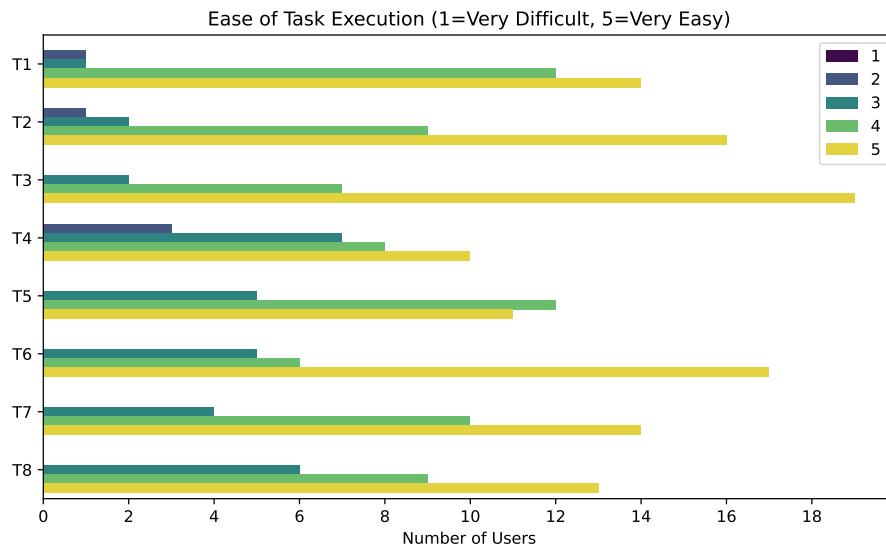

Figure 6.9: Perceived Task Ease among Participants.

Analyzing the graph in Figure 6.9, we can observe the overall ease of completing the tasks. The results indicate that the most difficult task was T4 – "Access to the main menu", likely because participants did not remember that it required pressing the back button on the right controller. Task T5 – "View object original appearance" with the slider, also presented difficulty, possibly due to the difficulty of interacting with the slider bar. It is important to note that this issue was later improved by making the entire slider bar visible and removing the need sometimes to cross the arms to move it. This improvement is further explained in Section 6.3.1.

The statements used to evaluate the tasks-related experience are as follows:

S1 – Exploration inside the tomb was intuitive.

S2 – Exploration outside the tomb was intuitive.

S3 – Navigation to points of interest was clear and accessible.

S4 – The slider was effective in showing object transformation over time.

S5 – I clearly distinguish between the artifact's original and restored state.

S6 – The information provided helped me better understand the artifact.

S7 – The experience contributed to a better understanding of the site.

S8 – The experience helped me better understand the presented artifacts.

S9 – The experience provoked a sense of presence in the historical site.

S10 – The tasks had a clear purpose and were easy to interpret.

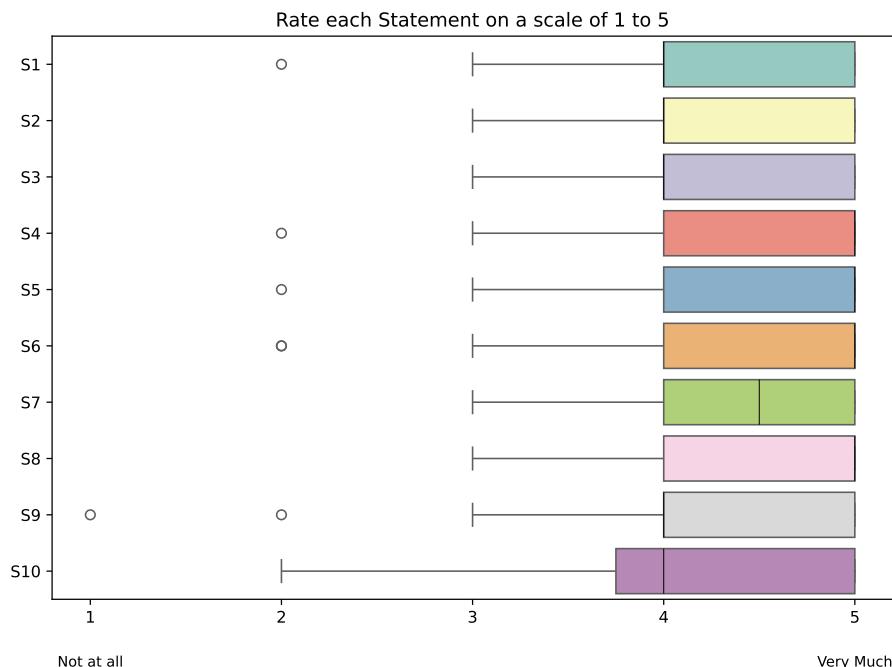

Figure 6.10: Participants' Agreement with Task-Related Statements.

The results shown in Figure 6.10 indicate a general agreement among users with the statements concerning their interaction, exploration, and navigation within the environment. In particular, statements 4, 5, and 6 received the highest levels of agreement, regarding the effectiveness of the slider in displaying transformations and the engagement of the information provided about the objects. The median values of all statements range between 4 and 5, highlighting a very positive outcome.

6.2.3 Presence Questionnaire (PQ)

The evaluation of presence was conducted using the Portuguese validated version of the Presence Questionnaire, adapted by Vasconcelos-Raposo et al. [44] was used, from which eleven items were removed "in order to improve the validity of the constructs and their internal consistency." The original Presence Questionnaire by Witmer et al. [49] consists of thirty-two questions, covering four major factor categories: Control, Sensory, Distraction, and Realism. In the translated version, ten of the twenty-one validated and translated questions were selected, as they were considered the most relevant for this research.

Questions addressing less important topics, such as sounds during the experience, were excluded. This questionnaire section was applied using a 5-point Likert scale.

The ten questions selected are the following:

- Q1 – How natural did your interactions with the environment seem?
- Q2 – How much did the visual aspects of the environment involve you?
- Q3 – How much did your experiences in the virtual environment seem consistent with your real world experiences?
- Q4 – How well could you actively survey or search the virtual environment using touch?
- Q5 – How involved were you in the virtual environment experience?
- Q6 – How proficient in moving and interacting with the virtual environment did you feel at the end of the experience?
- Q7 – How completely were your senses engaged in this experience?
- Q8 – Were there moments during the virtual environment experience when you felt completely focused on the task or environment?
- Q9 – How easily did you adjust to the control devices used to interact with the virtual environment?
- Q10 – Was the information provided through different senses in the virtual environment (e.g., vision, touch, hearing) consistent?

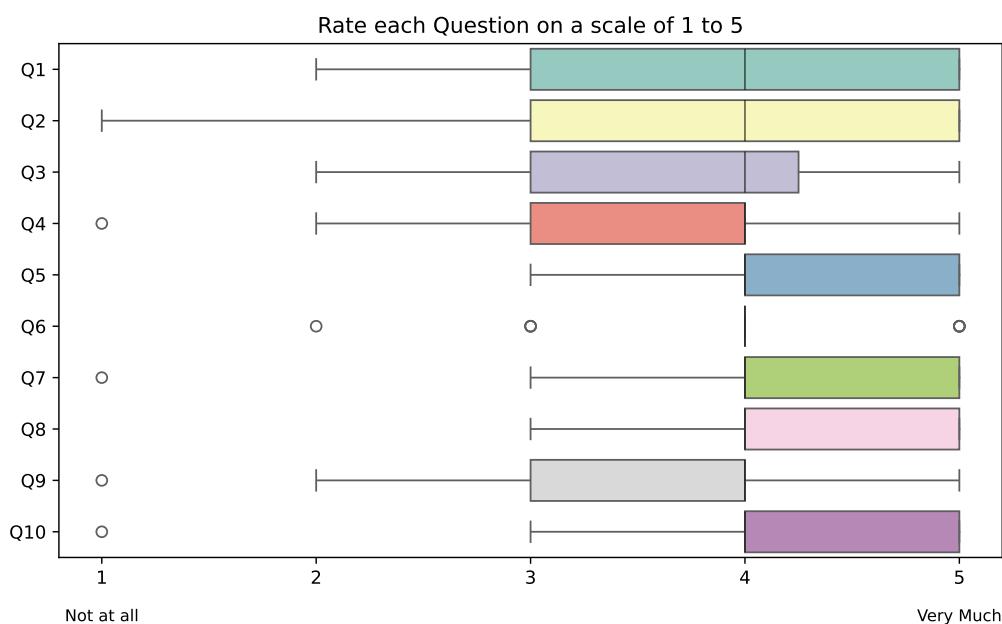

Figure 6.11: Perceived Sense of Presence among Participants.

Figure 6.11 represents the participants' sense of presence during this evaluation.

It is interesting to note that question 6 shows that quartiles 1, 2, and 3 coincide at the value 4. This indicates a very strong consensus among participants, with at least 50% reporting good navigation and understanding of the environment after the experience, reflected in a median score of 4 out of 5. Overall, most participants rated their proficiency as 4, showing strong agreement, with only a few outliers providing lower or higher ratings.

6.2.4 User Experience Questionnaire (UEQ-S)

The overall user experience was measured using the Portuguese version of the User Experience Questionnaire², constructed by Laugwitz et al. [22], and translated by Cota et al. [8].

The UEQ-S is the short version of the User Experience Questionnaire (UEQ), comprising a list of eight items selected from the original twenty-six. [37]. These items are grouped into two meta-dimensions, found in Annex I: pragmatic quality and hedonic quality, each containing four items. In addition, the mean value across all items is reported as an overall UX score. The questionnaire is structured around pairs of contrasting attributes that may describe the system. Participants provide their evaluation on a seven-point scale, where each circle represents a gradation between the two opposites.

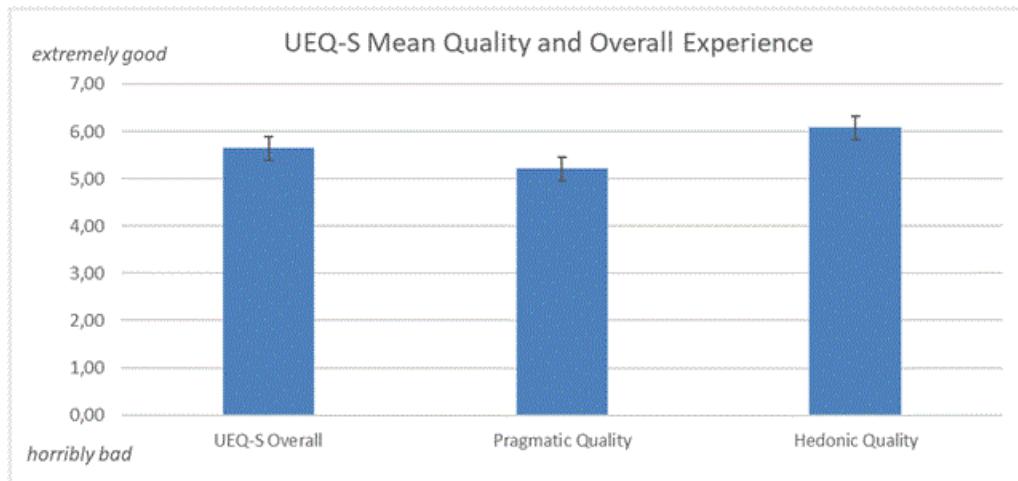

Figure 6.12: Overview of the UEQ Evaluation Distribution among Test Participants.

The UEQ results, as demonstrated in Figure 6.12, show a highly positive overall experience. The evaluation factor hedonic quality, reflecting user satisfaction and enjoyment, was particularly high, while pragmatic quality denoted the system's usefulness and effectiveness.

On a scale from -3 to 3, Figure 6.13 illustrates the mean responses of the participants per item. We can conclude that there is a good average, especially in the Hedonic Quality. The y-axis shows the list of UEQ items, with participants grouped by scale dimension:

²<https://www.ueq-online.org/>

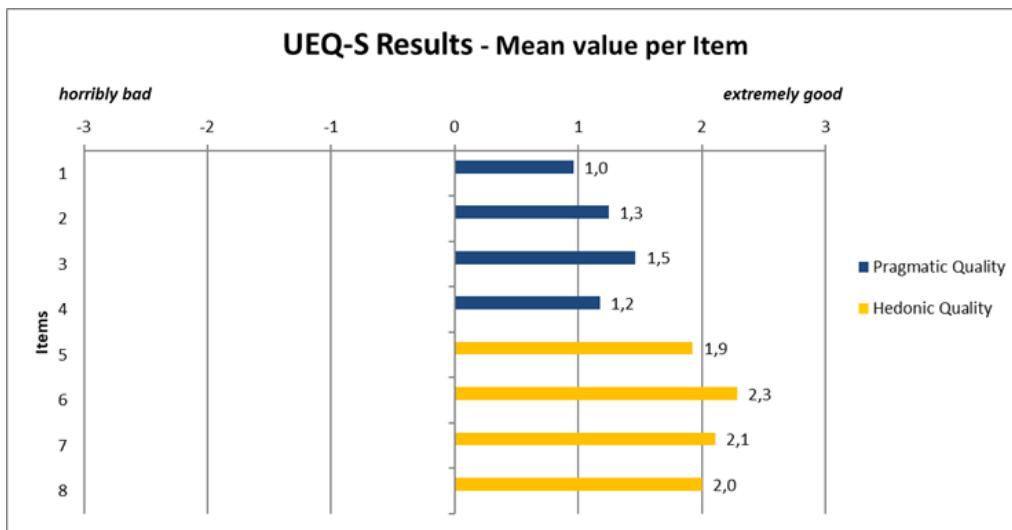

Figure 6.13: Mean value of UEQ Items of the Participants' Experience.

Table 6.1: UEQ Items, their Mean responses, Standard Deviations, and the corresponding Opposite Pairs by Scale.

Item	Mean	Std. Dev.	Negative	Positive	Scale
1	1,0	0,8	obstructive	supportive	Pragmatic Quality
2	1,3	1,0	complicated	easy	Pragmatic Quality
3	1,5	0,7	inefficient	efficient	Pragmatic Quality
4	1,2	1,3	confusing	clear	Pragmatic Quality
5	1,9	1,0	boring	exciting	Hedonic Quality
6	2,3	0,8	not interesting	interesting	Hedonic Quality
7	2,1	0,9	conventional	inventive	Hedonic Quality
8	2,0	0,9	usual	leading edge	Hedonic Quality

Pragmatic or Hedonic Quality. Table 6.1 supports this graphic with this and more relevant information of the UEQ used.

6.2.5 Participants Profile Comparison

The graph illustrated in Figure 6.14 compares agreement with statements, distinguishing participants with a background in Archaeology/Conservation from those in other fields. The error bars represent the standard deviation, indicating the variability in the responses. The statements correspond to the ones used on the y-axis of Figure 6.10, with a focus on those considered most meaningful for an Archaeology or Conservation/Restoration specialization. Those are:

- S5 - I clearly distinguish between the artefact's original and restored state.
- S6 - The information provided helped me better understand the artefact.
- S7 - The experience contributed to a better understanding of the site.
- S8 - The experience helped me better understand the presented artefacts.

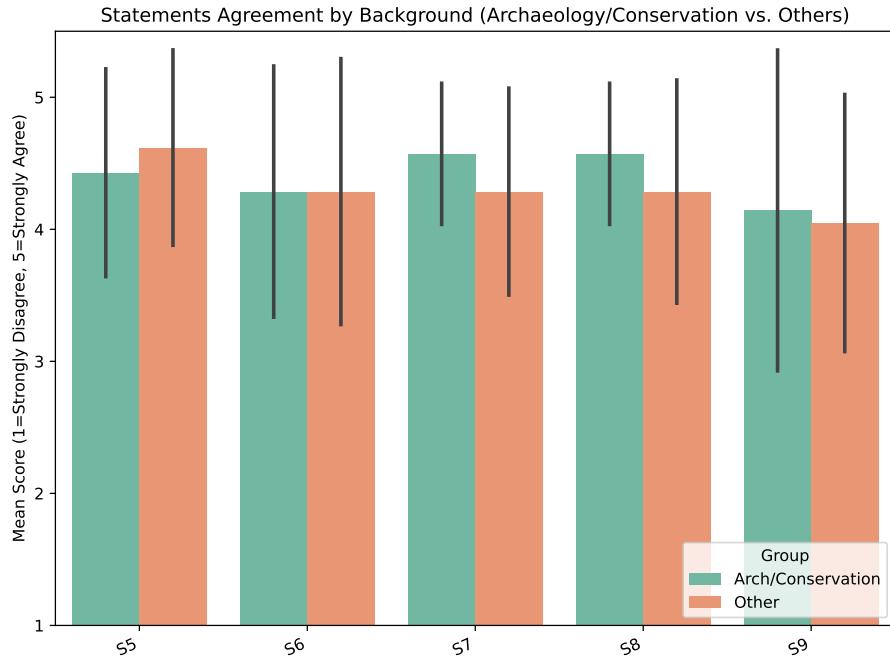

Figure 6.14: Comparison between Participant Groups, regarding Agreement with Statements about their Experience.

- S9 - The experience provoked a sense of presence in the historical site.

In general, as represented above, specialists provided a better average score to the statements, except statement 5, presumably due to the greater critical demand of professionals who have direct experience with artefacts in the field of conservation and restoration.

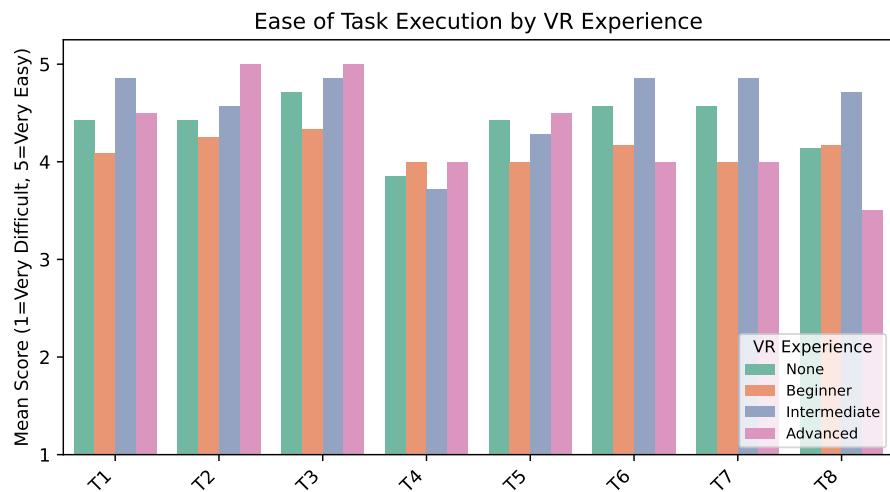

Figure 6.15: Ease of Task Execution according to Participants' VR Experience.

The results presented in Figure 6.15 indicate a general ease in completing the tasks among participants with higher levels of experience in VR. However, in some cases, the scores for the Intermediate group exceeded those of the Advanced group (specifically

in T1, T6, T7, and T8). This outcome may be explained by the fact that, as illustrated in Figure 6.7, only two participants were classified as "Advanced", representing a very small sample that may not provide fully reliable results.

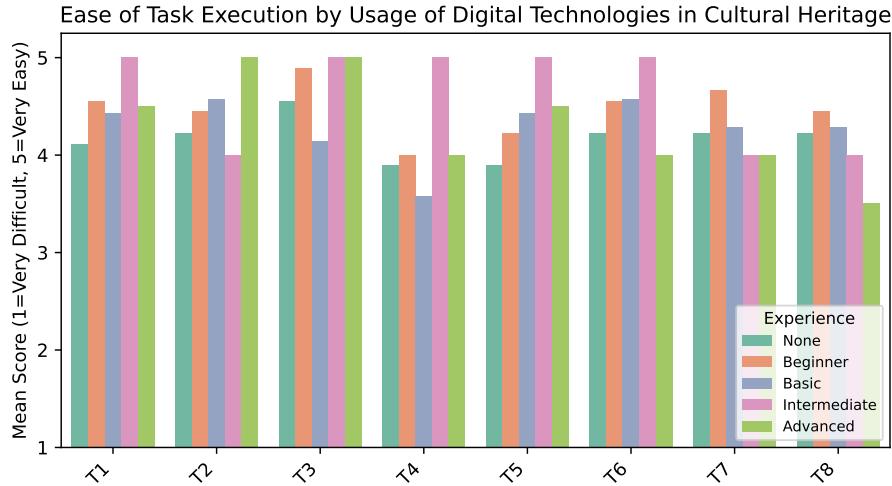

Figure 6.16: Ease of Task Execution according to Participants' Experience with Technologies applied to CH.

The bar chart in Figure 6.16 demonstrates that users with greater experience in technologies applied to CH generally found the tasks easier to execute, except for T7 – "Access a point of interest", and T8 – "Change the base (ground) plan".

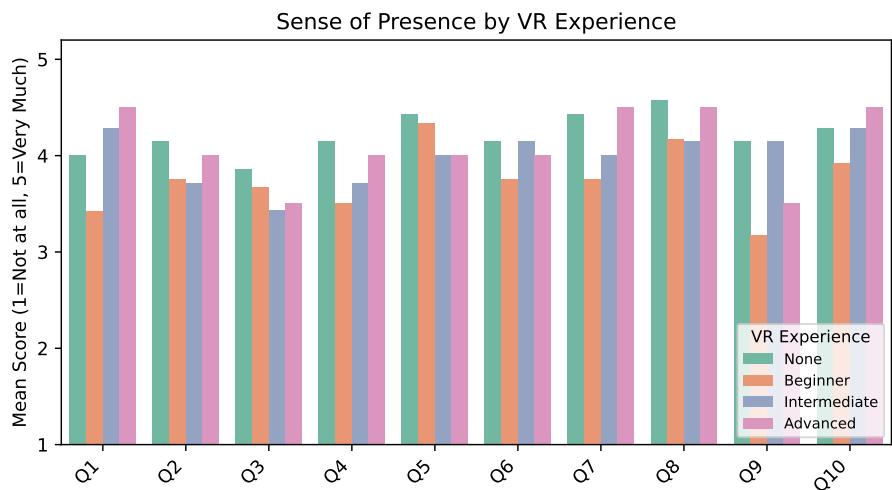

Figure 6.17: Participants' reported Sense of Presence according to their VR Experience.

In Figure 6.17, a bar graph illustrates the Sense of Presence results from the PQ, organized by participants' VR experience. Remarkably, users with no previous VR experience reported, in various questions (Q2, Q3, Q5, and Q8), a stronger sense of presence than those proficient.

6.3 Discussion

Overall, the results obtained of the User Analysis were balanced, showing a generally younger age group with higher education levels. Professional backgrounds were well distributed, with a larger proportion in Computer Science and Engineering, and Conservation and Restoration. Most participants had at least some prior experience with VR and in using digital technologies applied to CH. The tasks were generally completed with ease, as showed in Figure 6.9. In addition, the PQ results indicated a good median sense of presence among participants, and the UEQ reflected a very positive overall user experience as demonstrated by the mean. In Section 6.2.5, participants with specialist knowledge in Conservation and Restoration and Archaeology showed slightly higher average scores on statements related to their field, compared to others. As expected, prior experience with VR and in technologies associated with CH helped participants solve the tasks. Finally, the sense of presence was generally stronger when participants had previously engaged with VR, although there were some exceptions for certain PQ items.

6.3.1 Improvements After User Testing

Some minor improvements were made following user testing. These mainly concerned the UI and small implementation bugs:

- Enabled the possibility to activate or deactivate the model throughout the entire experience, rather than only the first time. Previously, the collider component that allowed this functionality was deactivated after the user entered the tomb.
- Allowed teleportation to the tomb icon even when the menu panel was open. Those were interfering, so previously, the teleportation was only possible when the panel was closed.
- Added a legend when selecting the correct option in the main menu to guide users.
- Simplified slider interaction: it is no longer necessary to cross the arms to move the slider. When grabbing the object with the right controller, the bar now correctly repositions on the corresponding side.
- Original Glass Texture Improvements: Adjusted parameters for object ID 2676. Enhanced the realism of the texture by adding a slight blue tint, as experts indicated that these Roman glasses tended to have a bluish hue.
- Tomb Interaction: Improved the definition of the tomb limits, increasing the coordinate precision on both sides.

CONCLUSIONS

The last chapter begins with an overview of the results achieved and functionalities developed, and their alignment with the intended goals, in Section 7.1. Section 7.2 enumerates possible future improvements, identifies limitations, and new ideas that could further evolve the system and provide a more complete user experience.

7.1 Final Overview

The system was developed with careful attention to the special Cultural Heritage (CH) artefacts and monuments of the archaeological site of Troia.

This work created a virtual representation of real objects and the funerary enclosure, constructing an immersive space inside the tomb that preserved the context of the artefacts, as intended in the goals described in Section 1.3 of the first chapter. The system provided an engaging user experience by displaying informative content through data panels. It also offered interactive features, such as grabbing objects, map teleport, exploration, and navigation within the realistic 3D funerary enclosure. Users often perceived the experience as finished after these interactions, even before opening the *Panel UI* for additional exploration.

The implementation concentrated on developing functionalities that enhanced immersion and interaction within the VR environment. The development of the tool in Unity took the most time during the implementation phase. The custom scripts focused primarily on user navigation within the plane, including tombstones, interaction with objects, and interaction with the data panels containing images before and after the intervention, as well as text, and interaction with the dropdown and checkboxes. Among the implemented features, the *Object Slider* enabled users to gradually transition an object between its original and restored states, representing one of the most innovative features of this work. This combination of immersion in an environment with artefacts, map layers, and cultural learning with the system fostered meaningful engagement with heritage content.

In parallel, the repository was designed with a base structure of 11 tables, although only two, “object” and “object_intervention”, were used in this study. Communication

between Unity and the Postgres database was established through a *Node.js* backend, which implemented two API requests. These enabled data exchange between Unity and the database using *UnityWebRequest*. All stored artefact attributes were validated in collaboration with conservation and restoration specialists. Some external tools supported the technical pipeline. *Agisoft Metashape* was employed in two key moments. At the beginning of the implementation, the 3D model of the funerary enclosure, together with its associated texture, was generated. In the final phase, the model's size was reduced to enhance efficiency. The use of *Blender* was challenging, particularly for designing a simulation of the original glass texture, given the limited references and prior experience.

Additionally, user evaluation played a crucial role in validating the system. Several minor improvements were made after the user evaluation phase. These modifications improved the UI and subtle interaction details that only became evident through user evaluation. Also, receiving feedback from domain experts was essential. The evaluation results, analysed in Chapter 6, confirmed a generally positive experience, and users gave interesting suggestions for future environment improvements.

Finally, another important outcome of this project was the dissemination of these developments: a short paper has been written and will be published soon.

7.2 System Limitations and Future Work

As this dissertation represents a first step toward a broader project, several future improvements are interesting. Some were identified during development, while others emerged from user feedback during the evaluation phase. These ideas are summarized below:

User Interaction

- **Hand Tracking vs Controllers:** Possibility to replace the controller-based interaction with hand tracking to provide a more natural and immersive experience, which would be particularly helpful for users less familiar with controllers.
- **Object Proximity Control:** Introduce a mechanism that allows users to control the distance they want when an object is grabbed. Currently, the distance is determined by how close the controller ray is when the user grabs the object.
- **Object Identification:** In the future, it would be interesting if, when grabbing an object, it would display object data when an object is grabbed, which would be more intuitive and easier to understand. An implementation had been tried, but not concluded, that consisted of showing the object's measurements in 3D when grabbed.
- **Tomb Navigation Control:** Add, for example, a button that explicitly places the user inside or outside the tomb to avoid the user entering the tomb when it is not wanted.

- **Plan Limits:** Add some warning safety bay, or a safety sign, or disable gravity outside the plan, to prevent users from falling off the plan.

User Interface

- **Dynamic Panels:** Allow Panel UI and Main Menu to open relative to the user's position and be repositioned dynamically, instead of remaining static. Additionally, the possibility for the user to move the Panel to another side if they desire.
- **Main Menu Improvements:** Expand the menu with additional options and improve usability.
- **Panel UI:** Possibility to view more detailed data, returning more information already stored in the database, and adding more backend requests to the system. Additionally, integrate in the Panel UI a link to related excavation findings or museum artefacts. This feature was developed and is working, but an additional paid library, such as 3D WebView¹ would be needed to open the link in the headset to the parallel museums with these findings. With the implementation made, the link only opens in the computer browser.
- **Search and Filter Features:** Add a user's search and filter objects' details feature based on fields, such as time period, shape, and provenance.

Environment & Immersion

- **Expand Environment:** Add more 3D object models and have further POIs with 3D models across the map.
- **Sound Design:** Provide a more complete experience with sounds, such as footsteps, ambient audio, and UI interaction effects. It already exists in some functionalities, but it is very little because it was not a priority.
- **Geospatial Data Integration:** Incorporate GIS layers, and georeferencing for richer spatial context, for example, in the excavation process, or objects location.
- **Extended Map Interaction:** Extend and improve map interaction, such as uploading an object after clicking on a position in the map and saving it in the *location* table, or an Algorithm to find the best route for the visit and provide directions, such as using direction arrows to guide users to historically significant locations.

¹<https://developer.vuplex.com/webview/overview>

Repository & Data Management

- **Document Upload/Download:** Allow contributors to upload images, videos, or excavation reports of the archaeological intervention.
- **Digital Preservation:** Add the usage of standard formats for the CH information stored in the database, such as the CIDOC-CRM, approached in the Chapter 2, Section 2.5.1.

Bug Fixes

- **Reticles Bug:** Address the issue of duplicate pink reticles appearing in the headset when the user is looking forward.

PORTUGUESE VERSION OF THE USER
EVALUATION QUESTIONNAIRE

Teste de Usabilidade e Presença no contexto da dissertação: "*Digital Tools for Studying Luxury Glassmaking in Roman Portugal*"

Este estudo procura avaliar a usabilidade de um sistema de **Realidade Virtual** desenvolvido no âmbito da dissertação "[Digital Tools for Studying Luxury Glassmaking in Roman Portugal](#)".

Inicialmente, serão recolhidas informações sobre os participantes para fins estatísticos.

De seguida, será convidado(a) a realizar um conjunto de tarefas no ambiente, que representa virtualmente uma parte das **Ruínas Romanas de Tróia**.

Por fim, será solicitada a sua opinião sobre a experiência. O questionário é anónimo e destina-se exclusivamente a fins académicos.

Tarefas

Está prestes a explorar uma reconstrução virtual de um **recinto funerário romano descoberto em Tróia**. Este encontra-se sobre um **plano base**, que contém o desenho duma parte deste sítio arqueológico.

Contexto:

Recinto funerário: Estrutura principal, que inclui a tumba.

Tumba: Parte do recinto, e contém 2 objetos de vidro para explorar.

Artefactos: Dois objetos que pertenciam ao defunto e que podem ser examinados de perto.

Slider: Barra interativa que permite visualizar a transformação do objeto, do estado original até ao atual.

Painel informativo: Fornece dados textuais sobre os objetos.

Galeria de imagens: Contém fotografias dos artefactos antes e depois da intervenção de restauro.

Pontos de interesse (âncoras azuis): Locais destacados que facilitam a navegação e permitem a observação de áreas específicas.

Instruções de Movimento:

Pode deslocar-se no ambiente virtual de duas formas: **movimento contínuo** ou **teletransporte**. Experimente e utilize a que lhe for mais confortável.

1. Movimento Contínuo – Caminhe pelo ambiente com o joystick esquerdo.

2. Teletransporte – Use o joystick direito girado para a frente, para se mover instantaneamente para um novo local.

Rotação Rápida (Snap Turn) – Altere o seu ângulo de visão movendo o joystick direito lateralmente.

Agarrar Objetos (Grab) – Use o botão lateral de qualquer comando para agarrar um objeto.

Selecionar – Pressione o botão A no comando direito.

Ativar/Desativar o modelo 3D da tumba – Aponte para a área da tumba e clique no trigger (botão traseiro) do comando esquerdo.

Ativar/Desativar o menu principal – Pressione o trigger (botão traseiro) do comando direito.

1. Ative o **modelo 3D da tumba**.
2. Caminhe até à tumba ou selecione o seu ícone azul para se teletransportar.
3. Dentro da tumba, aponte para um objeto até ver o **contorno e agarre-o**.
4. **Saia da tumba** com o objeto ainda na mão.
5. Com o objeto na mão, use o outro comando para **mover o slider** e visualizar a sua aparência original.
6. **Largue o objeto** ao deixar de pressionar o botão lateral do comando.
7. Teletransporte-se para um **Ponto de Interesse**, selecionando um dos ícones azuis.
8. Ative o **menu principal** e selecione o **ícone** visível com o comando direito.
9. Feche o menu principal.
10. No painel à sua frente, selecione o **Object ID 21684** e visualize as informações apresentadas.
11. Caminhe até ao painel azul e passe o cursor sobre as **setas** para visualizar as imagens do objeto **após da intervenção**.
12. No painel à sua frente, **altere o plano base**, selecionando a opção "**Toggle Layer**", e explore.

APPENDIX A. PORTUGUESE VERSION OF THE USER EVALUATION
QUESTIONNAIRE

Avaliação da Experiência					
Para cada uma das tarefas que realizou, indique numa escala de 1 (Muito difícil) * a 5 (Muito fácil) quanto fácil foi a sua execução.					
	1	2	3	4	5
Visualização da Informação textual do objeto	<input type="radio"/>				
Visualização da Galeria de Imagens	<input type="radio"/>				
Agarrar e manipular artefacto	<input type="radio"/>				
Acesso ao menu principal	<input type="radio"/>				
Ver aparência original do objeto com o slider	<input type="radio"/>				
Mover-se no ambiente (andar/teletransporte)	<input type="radio"/>				
Aceder a um ponto de interesse	<input type="radio"/>				
Alterar o plano base (do chão)	<input type="radio"/>				

Avalie cada afirmação numa escala de 1 (Nada) a 5 (Muito): *

1 2 3 4 5

A exploração dentro da tumba foi intuitiva.	<input type="radio"/>				
A exploração fora da tumba foi intuitiva.	<input type="radio"/>				
A navegação para o/os ponto/s de Interesse foi clara e acessível.	<input type="radio"/>				
O slider foi eficaz a mostrar a transformação do objeto ao longo do tempo.	<input type="radio"/>				
Consegui distinguir claramente entre o estado original e restaurado do artefacto.	<input type="radio"/>				

APPENDIX A. PORTUGUESE VERSION OF THE USER EVALUATION
QUESTIONNAIRE

As informações apresentadas ajudaram a compreender melhor o artefacto.	<input type="radio"/>				
A experiência contribuiu para uma melhor compreensão do sítio arqueológico.	<input type="radio"/>				
A experiência ajudou a compreender melhor os artefactos apresentados.	<input type="radio"/>				
A experiência provocou uma sensação de presença no local histórico.	<input type="radio"/>				
As tarefas tinham um objetivo claro e foram fáceis de interpretar.	<input type="radio"/>

Presence Questionnaire (PQ) - Avaliação da presença no ambiente virtual

Esta secção tem como objetivo avaliar o seu nível de envolvimento no ambiente virtual.

Indique o seu grau de concordância com as afirmações seguintes: (1 – muito baixo, 5 – muito alto)

1 2 3 4 5

Quão natural te pareceram as tuas interações com o ambiente?

Em que medida os aspetos visuais do ambiente te envolveram?

Quão consistentes te pareceram ser as experiências no ambiente virtual em comparação com as experiências do mundo real?

APPENDIX A. PORTUGUESE VERSION OF THE USER EVALUATION
QUESTIONNAIRE

Quão bem conseguiste inspecionar ou pesquisar ativamente no ambiente virtual utilizando o tato?	<input type="radio"/>				
Quão envolvido estiveste na experiência do ambiente virtual?	<input type="radio"/>				
Quão à vontade te sentiste no final de experiência em relação às ações de mover e interagir com o ambiente virtual?	<input type="radio"/>				
Quão completamente estavam os teus sentidos envolvidos na experiência?	<input type="radio"/>				

APPENDIX A. PORTUGUESE VERSION OF THE USER EVALUATION QUESTIONNAIRE

Houve momentos durante a experiência no ambiente virtual durante os quais te sentiste completamente concentrado na tarefa ou no ambiente?	<input type="radio"/>				
Quão facilmente te adaptaste aos dispositivos de controlo utilizados para interagir com o ambiente virtual?	<input type="radio"/>				
A informação fornecida através dos diferentes sentidos no ambiente virtual (p. ex., a visão, toque ou audição) foi consistente?	<input type="radio"/>

QUESTIONNAIRE

User Experience Questionnaire (UEQ)

A fim de avaliar o ambiente desenvolvido, por favor preencha a secção seguinte.
Marque a sua resposta da forma mais espontânea possível.

Não há respostas "certas" ou respostas "erradas". A sua opinião pessoal é que conta!

Esta questão é constituída por **pares de opostos** relativos às propriedades
inerentes ao ambiente desenvolvido. *

Ex: Atraente ● ○ ○ ○ ○ Feio

Esta resposta significa que avalia o produto **mais atraente** do que **feio**.
